ABSTRACT

Development of drug products from natural sources enable advantageous treatment and therapy options. Bioactive compounds in *Ganoderma lucidum* spore powder (GLSP) are known for vast antibacterial, antioxidant and anti-cancer properties. Herein, we studied the use of dual-probe ultrasound to extract triterpenoids from GLSP and further investigated the bioactivity of resulting products. FTIR results confirm the presence of key peaks although dual-probe ultrasound varied extraction efficacy. Response surface methodology (RSM) was used to optimize extraction conditions (55:28 for solvent to solid ratio, 10.38 seconds of ultrasound time and 94% v/v of ethanol concentration). HPLC-Q-TOF-MS confirmed the presence of 9 different compounds and in vitro tests confirm good biocompatibility. Extracts are shown to inhibit DPPH radicals, reaching a maximum ($61.09 \pm 1.38\%$) at triterpenoid concentrations of 600 $\mu\text{g/mL}$. Dual-mode assisted extraction provides an enhanced approach for active embedded fiber production on a scale favorable to industry when using optimized process parameters. Furthermore, triterpenoid extracts show antibacterial properties on *S. aureus* and *E. coli* with potential in antibacterial and anticancer applications.

Keywords: *Triterpenoids; dual-model ultrasound; antibacterial; antioxidant; biocompatibility.*

1. Introduction

There is increasing interest in the development and application of natural phytochemicals as potential chemo-preventive agents in the healthcare remit, in pharmaceuticals and cosmetics¹⁻³. Some phytochemicals have been evaluated and their potential in clinical use has been successfully portrayed. For example, paclitaxel analogs and vince alkaloids have been used in chemotherapy for decades⁴. *Ganoderma lucidum* is a traditional medicine that is commonly used to promote health and longevity, especially in Asia⁵. It is used to in a range of applications including tumor treatment⁶, anti-aging effects⁷ and in the prevention of neurological diseases⁸. *G. lucidum* spore powder (GLSP) is the spores of the *G. lucidum*. These spores are small oval germ cells that are expelled from the fungi during growth and maturation⁹. They contain all the genetic material of *G. lucidum* and therefore have all the health benefits¹⁰. Recent research has confirmed that *G. lucidum* spores (GLS) have multiple functions including blocking histamine release, inhibiting the over-stimulated immune system, and regulating cell and humoral immunity¹¹⁻¹³. These results demonstrate that GLS have a variety of physiological functions related to the diversity of its biologically active components^{14, 15}. GLS contains many biologically active ingredients such as triterpenoids, polysaccharides, alkaloids, amino acids, enzymes and proteins^{16, 17}. Triterpenoids, a main component of GLSP, have been found to have a wide range of pharmacological activity¹⁸. There are very few studies concerning extraction of

triterpenoids from GLSP and therefore it is important to explore its constituents and bioactivity.

There are various methods that are used to extract compounds including but not limited to reflux, maceration and soxhlet extraction. Conventional extraction methods for triterpenoids are time consuming and utilize excessive volumes of solvent and achieve low extraction rate¹⁹. In contrast, ultrasound-assisted extraction (UAE) techniques present a sustainable alternative extraction method using less solvent and energy²⁰. Acoustic cavitation induced by ultrasound is capable of breaking cell walls of plant matrix, enhancing the release of bioactive compounds from the matrix²¹. Ultrasonic-assisted extraction has many advantages over more conventional methods, including but not limited to shorter processing times, reduced solvent usage, higher extraction rates, more economical extraction processes and improved product purity²². Process parameters and solvent parameters affecting the extraction rate of ultrasonic extraction include feed-to-liquid ratio, solvent concentration, ultrasound time and ultrasound frequency. Recently, multi-mode ultrasound has been presented as an effective method to improve product extraction rates²³. While ultrasound extraction may be expected to improve the extraction yield, triterpenoid compounds obtained from GLSP using two different frequencies ultrasonic treatment for a higher extraction rate is needed.

Response Surface Methodology (RSM) is an effective statistical tool for optimizing complex processes²⁴. It is widely used to optimize the extraction of polysaccharides²⁵, anthocyanins²⁶, phenolic compounds²⁷, proteins²⁸ and triterpenoids²⁹ from different

plant materials. However, RSM can be applied to optimize species-specific compound extraction using ultrasonic parameters (i.e. extraction temperature, power percentage and exposure time).

In this study, the main objective was to investigate the effect of UAE variables (solvent to material ratio, ultrasound time and concentration of ethanol) using two different frequency probes for ultrasound-assisted triterpenoids extraction from GLSP. Two different probe positions were assessed; parallel and perpendicular. The values of the variables were then optimized using RSM to obtain the maximum yield of total triterpenoids in GLSP. Subsequently, component detection and bioactivity characterization of the extracted compound was performed. In order to study triterpenoid antioxidant activity, a DPPH experiment was carried out and antibacterial activity was analyzed using the disk diffusion method. The biocompatibility of extracts to L929 cells and Hela cells was also examined.

2. Materials and methods

2.1 Materials and reagents

Dried GLSP was received from Tianhe Agriculture Group (Zhejiang, China). Ethanol and glacial acetic acid were purchased from Taicang Shanghai Test Reagent Co., Ltd. (Jiangsu, China). Perchloric acid was purchased from Shanghai Wokai Biotechnology Co., Ltd. (Shanghai, China). Oleanolic acid was purchased from Adamas-beta (Shanghai, China). Vanillic was purchased from Shanghai Aladdin Bio-Chem

Technology Co., Ltd, LTD (Shanghai, China). All the reagents used were analytical grade.

2.2 Ultrasound-assistant extraction

In the study, two different frequency ultrasonic generators were used to assist in triterpenoids extraction. A schematic diagram of the experimental setup of dual ultrasound extraction device is shown in **Figure 1**. Two transducers, U_1 ($\Phi = 13$ mm, 20 kHz, 200 W, Sonifier 250, Branson Ultrasonics Co., Ltd) and U_2 (13 mm, 15 kHz, 600 W, Shanghai Yanyong Ultrasonics Co., Ltd), were used.

In order to investigate effect of the position between two transducers, they were fixed at transversal position U_1 and U_2 . For parallel treatment, U_2 was moved to the position of U_2^* , as shown in **Figure 1**. The metal container ($205 \times 205 \times 200$ mm) was filled with water. The effects of the relative position of the two probes were compared.

Four factors were selected to analysis their effect on the yield of triterpenoids from GLSP through single-factor experiments: 1) relative position of dual frequency, 2) solvent to material ratio, 3) ultrasound time, and 4) concentration of ethanol. During the entire experiment, when one factor was changed, the other three factors were kept constant. Different concentrations of ethanoic solutions were prepared by blending ethanol with distilled water.

2.3 Fourier transform infrared spectroscopy

Fourier Transform Infrared (FTIR) spectroscopy (IR Affinity 1, Shimadzu, Japan) was used to compare the effects of different number of ultrasound probes and relative

position on the chemical structure of extract. Samples were prepared using the KBr pellet pressing method using 20 MPa of pressure and were scanned across the range was 4000-400 cm^{-1} ³⁰.

2.4 Experimental design

2.4.1 Box-Behnken Design

Box-Behnken Design (BBD) was used to determine the optimal conditions of UAE. The study of the influence of all the defined independent variables was carried out using a one-factor-at-a-time program; to determine the initial range of the processing variables. Based on the above single-factor results, three major independent variables were selected: solvent to solid ratio (A), ultrasound time (B, min), ethanol concentration (C, %). The independent variables and their related codes and levels are displayed in **Table 1**. The experimental design consisted of 12 factorial experiments and 5 replicates of the central point (**Table 2**). The yield of triterpenoids was selected as the response for the combination of independent variables given in **Table 2**. In order to minimize the unpredictable effects in the observed responses, experimental runs were random.

2.4.2 Mathematical Model

The response surface models were fitted by means of least-squares calculation using the following second-order polynomial equation:

$$Y = a_0 + b_1A + b_2B + b_3C + c_{12}AB + c_{13}AC + c_{23}BC + d_1A^2 + d_2B^2 + d_3C^2 \quad (1)$$

Where Y is the predicted response; a_0 is the interception; b_1 , b_2 and b_3 are the linear coefficients of solvent to solid ratio (A), ultrasound time (B) and ethanol concentration

(C), respectively; c_{12} , c_{13} , and c_{23} are the interaction coefficient of solvent to solid ratio, ultrasound time and ethanol concentration, respectively; d_1 , d_2 and d_3 are the squared coefficient of solvent to solid ratio, ultrasound time and ethanol concentration, respectively.

Statistical analysis was performed using the software Design Expert (Version 8.0.6, Stat-Ease Inc., Minneapolis, MN, USA). Additional confirmation experiments were subsequently conducted to verify the statistical experimental design.

2.5 Determination of total triterpenoids content

The total triterpenoids content was measured by the Vanillin-glacial acetic acid method³¹. Oleanolic acid was used as a standard. A standard curve (for triterpenoids) was obtained using UV analysis at a wavelength of 545 nm. The total content of triterpenoids was calculated from the standard curve. A linear correlation relationship between absorbance and concentration was obtained as shown in **Figure 1b**.

The equation for the linear relationship is as follows:

$$A = 6.22C - 0.0298, (R^2 = 0.998) \quad (2)$$

Where C (mg/mL) is the concentration of triterpenoids solution and A is the absorbance at 545 nm.

Equation 2 was used to calculate the yield of triterpenoids:

$$Y = (A + 0.0298) / 6.22 \times v / m \times 100 \% (\% \text{ w/w}) \quad (3)$$

Where v is the total volume of extraction solvent (mL), and m is the mass of triterpenoid extract sample (g).

2.6 HPLC-Q-TOF-MS analysis

As stated in the literature ³², in order to identify the compounds being extracted using ultrasound assisted method, a Fast High Performance Liquid Phase-Quadrupole Time-of-Flight (Q-TOF) Mass Spectrometer (AB Sciex Triple TOF 5600+, AB Sciex, USA) was used. The mass range (m/z) of the instrument was 50-10000 m/z, and the resolution was greater than 40000.

2.7 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity

A spectrophotometric method was used to analyze the antioxidant activity of triterpenoids on the basis of free radical DPPH according to previous papers with a slight modification ³³. Firstly, 0.2 mM DPPH and samples with different concentrations from 0 to 600 µg/mL were prepared in ethanol solution. Then equal amount (100 µL) of DPPH and the sample was mixed. After 30 min at room temperature, the absorbance of all samples was measured at a wavelength of 517 nm using a microplate reader (spectra Max 190, Nano Drop, USA). The results were expressed as a percentage reduction absorbance shown by the sample with respect to the control DPPH solution (ethanol and DPPH solution).

The formula used to calculate this is as follows:

$$\text{DPPH scavenging (\%)} = [(\text{control absorbance} - \text{sample absorbance}) / \text{control absorbance}] \times 100. \quad (4)$$

2.8 Antimicrobial activity

The antimicrobial activity of the extract of triterpenoids against *Escherichia coli* (NW1014 (8099), Nanjing Maojie Microbiology Technology CO. LTD, Jiangsu, China) and *Staphylococcus aureus* (CMCC(B)26003, Shanghai Luwei Microbial SCI. & TECH. CO. LTD, China) was examined using the disc diffusion method³⁴. Firstly, five circular paper pieces with diameters of 8 mm were placed on agar plates. Two different bacteria (which had been cultured for 24 h) were inoculated on the agar plates.

Different volumes of extract (2 μ L, 4 μ L, 6 μ L, and 8 μ L) were introduced to each paper disc; with the central disc void of extract to act as the control. The plates were incubated at 37°C for 24 h. The diameter of the zone of inhibition around each paper was used to determine the susceptibility of the extract. Both experiments were performed five times in parallel and the values were expressed as mean $\pm$ standard deviation (SD).

2.9 Cell culture

The L929 cell were cultured in a Modified Eagle's Medium (MEM, Gino Biomedical Technology Co., Ltd., China) supplemented with 10% Fetal Bovine Serum (FBS, Gibco), 1% antibiotics (Penicillin 100 U/mL, Streptomycin 100 μ g/mL). The Hela cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM, Corning, USA) supplemented with 10% Fetal Bovine Serum (FBS, Gibco), 1% antibiotics (Penicillin 100 U/mL, Streptomycin 100 μ g/mL). All cells were cultured in an incubator in 5% CO₂ at 37°C.

2.10 Cell viability analysis (L929)

The effect of triterpenoids on L929 cell viability with a CCK-8 assay was investigated. Firstly, different amounts of the triterpenoid extract were added to the MEM medium to prepare medicated medium with concentrations of 0.01, 0.05, 0.1, 0.2, 0.4, 0.6, 0.8 mg/mL. L929 cells (grown in log phase) (100 μ L) were introduced into 96-well plates and cultured for 24 h to adhere the cells. The original medium was removed and the medium containing the triterpenoid extract was replaced and cultured for 24 h.

The medium was mixed with CCK-8 at a ratio of 10:1. After 24 h, the previous medium was removed and 100 μ L of the mixture was added to each well and the plate was cultured in an incubator. The absorbance was measured with a microplate reader at pre-determined time points. The cell survival rate was calculated as follows:

$$\text{Cell survival rate} = [(As - Ab) / (Ac - Ab)] \times 100\% \quad (5)$$

As: Experimental well (cell-containing medium, CCK-8, triterpenoid extract)

Ac: Control well (cell-containing medium, CCK-8, no triterpenoid extract)

Ab: Blank well (a medium free of cells and triterpenoid extract, CCK-8)

2.11 Cell morphology observation (L929)

As described previously³⁵ cells were obtained using the same procedure as stated in 2.10. Following removal of the cells from the incubator, the medium was removed from the dish and the cells were rinsed with PBS. 4% paraformaldehyde was then added and then were agitated for 60 minutes at 60rpm. 0.1% Triton was then introduced to the cells and they were agitated for an additional 5 minutes at 60rpm. Following this treatment, the cells were rinsed 3 times with PBS; 5 minutes each time. Finally, the

cells were stained with two different fluorescent dyes; the cytoskeleton was stained with Phalloidin (P) for 20 minutes and 60 rpm and the nucleus was stained with DAPI for 5 minutes at 60rpm. The final stained cells were then observed under a fluorescence microscope.

2.12 Anticancer activity (Hela)

The effect of triterpenoids on Hela cell viability was studied with a CCK-8 assay. The Hela cells were cultured in DMEM medium. The cell survival rate experimental set-up was as described in 2.10 and the Hela cell staining experiment steps were as described in 2.11.

2.13 Statistical analysis

All experiments were performed in triplicate and the results were expressed as mean value $\pm$ standard deviation. In this study, t-test and ANOVA tests were performed. The statistical analysis was carried out using Origin Pro 2017 and Excel 2016. Excel 2016 was used to process the experimental data, and Origin Pro 2017 was used to organize the data into graphs. $P < 0.05$ was considered to be significant.

3. Results and discussion

3.1 Optimization of ultrasound-assisted extraction

In recent years, UAE of compounds has been applied to a wide range of applications. UAE improves the mass transfer of the extraction process due to the cavitation effect in the material. When cavitation bubbles are generated and subsequently collapse, the

cell walls of the material are destroyed and this promotes the release of solutes ³⁶. In this study, impact of four different factors (relative position of two ultrasound probes, solvent to material ratio, ultrasound time and concentration of ethanol) on triterpenoids yield was studied.

3.1.1 Effect of relative position of two ultrasound probes

As shown in **Figure 1(a)**, the effects of different probe positions were compared in dual frequency; one is parallel and the other is vertical. The ultrasound power of both probes was 180 W operating at two different frequencies; 15 kHz and 20 kHz. Ultrasound treatment was carried out for 10 minutes and the solvent to material ratio was kept at 1:50. 95% v/v ethanol was used and both ultrasonic probes were 4 cm from the extract. When the probes were kept in parallel, the yield of triterpenoids was $0.59 \pm 0.01\%$. However, when the relative positions of the probes were vertical, the extraction rate increased by 47%; yielding $0.87 \pm 0.04\%$ of extract. Based on these results, the two ultrasound probes were kept in vertical position for the following experiments.

3.1.2 Effect of solvent to material ratio

It is vital to optimize the solvent to material ratio as if it is too low, it will discourage mass transfer rate ³⁷. On the other hand, a high solvent to material ratio can induce prolonged distance of diffusion towards the interior substance ³⁸. This subsequently can interfere with its dissolution rate. Therefore, the optimal ratio needs to be established. The results were shown in **Figure 2(a)**. The concentration of ethanol was 95% v/v. The ultrasound time was 10 min. Both probes had ultrasound power of 180 w. The

frequency was 15 KHz and the other was 20 KHz. The relative positions of the two ultrasound probes were vertical. Both ultrasonic probes are 4 cm away from the extract. From the **Figure 2(a)**, it can be observed that when the solvent to material ratio was modified from 20:1 to 50:1 mL/g, the yield of triterpenoids improved gradually. Once the ratio was 60:1, the yield was constant; with no change upon using more solvent. Considering solvent savings, a ratio of 50:1 mL/g was selected as the optimum solvent to material proportion.

3.1.3 Effect of ultrasound time

The time of ultrasound treatment is also critical in this study. Here, the period of ultrasound application was varied between 1 and 30 minutes whilst all other factors were kept constant: Solvent to material ratio = 50:1, concentration of ethanol = 95% v/v, ultrasound power of both probes: 180 w and frequencies of 15 KHz and 20 KHz.

Figure 2(b) demonstrates that when increasing the ultrasound time from 1 minute to 10 minutes, the extraction rate gradually increased. When using an ultrasound treatment time of 10 minutes, the highest yield of triterpenoids was achieved ($1.38 \pm 0.04\%$). Prolonging the treatment time beyond 10 minutes caused the yield to decrease; indicating possible degradation of triterpenoids. There was a similar phenomenon when extracting quercetin in *Nasturtium officinale* ³⁹. As a result of this, an ultrasound treatment of 10 minutes was selected as the optimal time.

3.1.4 Effect of concentration of ethanol

The concentration of the solvent used in the extraction process may affect the extraction rate or the yield and therefore needs to be studied. Ethanol was chosen as the solvent in this study based on the principle of similar compatibility and that triterpenoids are polar compounds ⁴⁰. **Figure 2(c)** shows that the concentration of the solvent does have an effect on triterpenoid yield. When ethanol concentration increased from 70 to 95% v/v, the yield of the extract increased from $0.52 \pm 0.034\%$ to $1.43 \pm 0.0084\%$. These results can be described based on the “like dissolves like” theory: as the concentration of ethanol increased, the polarity of the solution also increased in turn increasing the extraction rate ⁴¹. A maximum triterpenoid yield was achieved when using an ethanol concentration of 95% v/v and this value was selected for all subsequent experiments.

3.2 FTIR

In order to study the effects of the relative position of dual-frequency ultrasound extraction on the structure of triterpenoids FTIR analysis was carried out. The resulting spectra is shown in **Figure 3**. Oleanolic acid was used as a reference and had several distinctive peaks. The peak at 3459 cm^{-1} corresponds to OH stretching bond, while the peak at 2293.98 cm^{-1} was as a result of a CH₃-(aliphatic) asymmetric stretching vibration bond. Peaks at 2859.38 cm^{-1} and 1689.31 cm^{-1} were due to CH₃- (aliphatic) symmetric stretching and CO stretching vibration bonds, respectively. The deformation for CH is seen as a peak at 1161.1 cm^{-1} , and the asymmetric CH₃-deformation peak can be observed at 1461.66 cm^{-1} ⁴².

Here, single-frequency ultrasonic extraction, dual-frequency vertical ultrasonic extraction and dual-frequency parallel ultrasonic extraction. When compared to the reference, similar peaks can be observed for all three extraction methods. Peaks at 2859.38 cm^{-1} , 1868.31 cm^{-1} and 1461.66 cm^{-1} are consistent with oleanolic acid. One thing to note here the extracted triterpenoid content. As this is quite low, some peaks may not be identifiable due to weak transmission. Regardless, the FTIR results confirm that none of three extraction methods compromised the structure of the extracted triterpenoids.

3.3 BBD for optimization of effective parameters

The Box-Behnken Design (BBD) model was used to study any interactions between variables: solvent to solid ratio (A), ultrasound treatment time (B) and ethanol concentration (C). The optimal experimental conditions were determined from the BBD model. The second order quadratic model was expressed by the following equation.

$$Y = 1.21 + 0.079A + 8.750 \times 10^{-3}B - 0.022C + 2.500 \times 10^{-3}AB - 0.025AC + 0.010BC - 0.078A^2 - 0.058B^2 - 0.14C^2 \quad (6)$$

To verify the significance and adequacy of the model, an analysis of variance (ANOVA) was performed (**Table 3**). A high F-value (F model = 19.19) and a low probability value (P model = 0.0004) indicated that the model was significant. The lack of fit term was not significant (p value 0.2531), which suggested the model equation was sufficient to predict the yield of ultrasound extraction when the relative probe position was vertical. The high R^2 value (0.9610) implied that the experimental and predicted values

correlated highly. This means that 96.1% of the total variation in the response could be explained by the model⁴³.

Figure 4 shows the 3D and 2D surface plots between every two independent variables.

Figure 4(a) and **(d)** show three-dimensional and two-dimensional response surface plots for interactive effects of solvent to solid ratio and ultrasound time on response values at fixed ethanol concentration. When the ultrasound treatment time was fixed, the yield of triterpenoids rapidly increased with the increase of the solvent to material ratio. After reaching the optimal maximum, the yield slowly decreased. A similar trend was observed when fixing the solvent to solid ratio. From **Figure 4(b)** and **(e)**, it can see that the effect of ethanol concentration on the yield of triterpenoids is not obvious when compared with the ratio of liquid to liquid. As shown in **Figure 4(c)** and **(f)**, compared with the ultrasound time, the effect of ethanol concentration on the yield of triterpenoids is more significant.

A variety of factors can be assessed using the Box-Behnken Design in order to select the suitable process parameters in practice⁴⁴. To assess the optimum conditions for the maximum yield of triterpenoids, three variables (solvent to solid ratio, ultrasound time and ethanol concentration) were set to the studied range. The Box-Behnken Design and analytical software suggested the optimal process conditions of ultrasound-assisted extraction of triterpenoids were as follows: a solvent to solid ratio of 55:28, 10.38 minutes of ultrasound time and 94% v/v of ethanol concentration. The yield of triterpenoids under such conditions was theoretically predicted to be 1.23%. The

experiments at the predicted optimum conditions were carried out in triplicate. The average value was 1.15%, confirming the validity and adequacy of the model.

3.4 Triterpenoid profiles by HPLC-Q-TOF-MS

Representative HPLC chromatographs of triterpenoids extract obtained at optimized parameters are shown in **Figure 5**. Triterpenoid extract contained 10 major compounds.

As shown in **Figure 5(a)**, there was ganocochlearin B (peak 1), ganoderic acid I (peak 2), lucidenic acid D (peak 3), ganoderenic acid D (peak 4), ganodernoid C (peak 5), ganoderic acid DM (peak 6) and ganodermic acid TQ (peak 7). In **Figure 5(b)**, we could see ganoderenic acid D (peak 1), ganoderiol I (peak 2) and ganoderic acid C2 (peak 3).

These peaks show mainly the ganoderma triterpenoids in ethanol. **Figure 6** shows the chemical structures of the components identified in ethanol. From these results, it was apparent that tetracyclic triterpenoids were the main compounds present in the ethanol extracts.

3.5 The radical-scavenging activity

The radical scavenging activity of the extracted compounds was evaluated by comparing the percentage inhibition of DPPH radicals between samples and the control.

As seen in **Figure 7**, the scavenging activities increased with the increase in triterpenoids concentration. The percentage of scavenging was only $34.52 \pm 1.41\%$ when using a concentration of 100 $\mu\text{g/mL}$ of triterpenoids. This increased and reached a maximum ($61.09 \pm 1.38\%$) when using a triterpenoid concentration of 600 $\mu\text{g/mL}$.

These results show that the extracted compound exhibited mild radical scavenging activity.

3.6 Antimicrobial activity

The antimicrobial activity of the extracted triterpenoids was assessed using two bacteria; *Escherichia coli* and *Staphylococcus aureus* and the resulting data is shown in **Figure 8**. The control group was void of triterpenoids. It is clear to see that the diameter of the zone of inhibition increased as the concentration of triterpenoids increased. **Figure 8(a)** showed that when the volumes of triterpenoids were 2 μ L, 4 μ L, 6 μ L, and 8 μ L, the average inhibition zone diameter for *E. coli* were 10.34, 10.36, 11.04 and 11.69 mm, respectively. Similarly, **Figure 8(b)** shows the antibacterial activity of triterpenoids against *S. aureus* at different volumes. These studies revealed that the mean zones of inhibition were 10.65, 11.06, 11.74 and 11.83 mm for volumes of 2 μ L, 4 μ L, 6 μ L, and 8 μ L, respectively. As can be seen in both **Figure 8(a)** and **8(b)**, when the volume of the triterpenoids was 6 and 8 μ L, the diameter of the inhibition zone was significant ($p < 0.05$). *E. coli* is a Gram-negative bacterium and *S. aureus* is a model Gram-positive bacterium. To date, most antibacterial medicinal plants are active against Gram-positive bacteria but very few against Gram-negative bacteria due to the difference in susceptibility between them ⁴⁵. From these experimental results, triterpenoids have demonstrated broad-spectrum antibacterial properties and can therefore be used to develop new antibacterial drugs.

3.7 Cell viability assays

Figure 9 highlights the effect of modifying triterpenoid concentration on cell viability of L929. Concentrations ranging from 10 to 800 $\mu\text{g/mL}$ were studied. **Figure 9(a)** shows that increasing triterpenoid concentration from 10 to 200 $\mu\text{g/mL}$, cell viability also increased gradually; from 107.67% to 122.13%. This suggested that triterpenoids (concentration less than or equal to 200 $\mu\text{g/mL}$) had adequate biocompatibility with L929 cells. However, surpassing this optimal concentration saw cell viability decrease slowly, falling to 82.49% when assessing triterpenoid concentration of 800 $\mu\text{g/mL}$. This illustrates that the triterpenoids caused weak toxicity to L929 cells in high concentrations.

In order to observe the effect of triterpenoids on L929 cell morphology, a fluorescent staining experiment was performed (**Figure 9(b)**). From the figure, it can be seen that the cells show a full oval or fusiform shape. When compared to the control, there is no significant difference in cell morphology following treatment with the extracted triterpenoids. Increasing extract concentration from 10 to 200 $\mu\text{g/mL}$ resulted a significantly higher number of cells with smaller cell spacing, indicating good biocompatibility. Increasing the triterpenoid concentration to 800 $\mu\text{g/mL}$ resulted in a reduced number of cells with a small number of round cells being present; further highlighting the toxicity of triterpenoids to cells at high concentrations.

3.8 Anticancer activity (Hela)

Among various cancers, cervical cancer is placed at second most common malignant tumor in women worldwide ⁴⁶. As described by the other authors ⁴⁷, *G. lucidum*

triterpenoid extract induces apoptosis in human colon carcinoma cells. Few studies have reported the effects of *G. lucidum* triterpenoids on cervical cancer in humans. In this study, the effect of different concentrations of triterpenoids on cell viability of Human Cervical Carcinoma Hela cells was evaluated. Extract concentrations ranged from 10 to 800 µg/mL. From **Figure 10(a)**, it is clear to see that when the concentration of triterpenoids was low (i.e. from 10 to 100 µg/mL), cell toxicity was also weak and the cell survival rate increased. Cell viability was 99.98% when using a triterpenoid concentration of 100 µg/mL. However, cell viability decreased with increasing concentrations (≥ 200 µg/mL) of triterpenoids. At a concentration of 800 µg/mL, the cell survival rate was only 51.66%, demonstrating the potential anticancer properties of the extracted triterpenoids.

Figure 10(b) presents fluorescent staining images under the effect of triterpenoids on L929 cell morphology. The morphology of cells treated by triterpenoids showed no significant difference to the control. The cells presented irregular fusiform morphology. When the concentration of triterpenoids was 100 µg/mL, there was no significant difference compared with the control but when assessing a concentration 800 µg/mL, the number of cells was significantly reduced and round cells were present; mimicking the results found with the cell viability results.

When comparing the effects of triterpenoids on the viability of Hela and L929 cells, it can be concluded that when a low concentration of triterpenoids is used, it can promote normal cell growth and with weak inhibitory effects on Hela cells. When the

concentration of triterpenoids was high, it was weakly toxic to normal cells, but it has a significant inhibitory effect on Hela cells. Therefore, it's a promising role as an effective chemotherapeutic agent against human cervical cancer.

4. Conclusion

Here, triterpenoids were successfully extracted from GLSP by using a dual ultrasound transducers-assisted method. RSM was used to optimize three different factors related to extraction; presenting the following optimal values: solvent to solid ratio: 55:28, ultrasound treatment time: 10.38 and ethanol concentration: 94% v/v. In addition, 9 different compounds found in triterpenoids were confirmed by HPLC-Q-TOF-MS. The extracted triterpenoids demonstrated the inhibition of DPPH radicals, reaching a maximum ($61.09 \pm 1.38\%$) at concentration of 600 $\mu\text{g/mL}$. In addition to this, the triterpenoids extract showed broad-spectrum antibacterial properties ($p < 0.05$) on *S. aureus* and *E. coli* alongside good biocompatibility with potential in antibacterial and anticancer applications.
