Abstract

Background

Colorectal cancer is the third most commonly diagnosed cancer worldwide. A diagnosis of colorectal cancer and subsequent treatment can adversely affect an individual's physical and mental health. Benefits of physical activity interventions in alleviating treatment side effects have been demonstrated in other cancer populations. Given that regular physical activity can decrease the risk of colorectal cancer, and cardiovascular fitness is a strong predictor of all-cause and cancer mortality risk, physical activity interventions may have a role to play in the colorectal cancer control continuum. Evidence of the efficacy of physical activity interventions in this population remains unclear.

Objectives

To assess the effectiveness and safety of physical activity interventions on the disease-related physical and mental health of individuals diagnosed with non-advanced colorectal cancer, staged as T1-4 N0-2 M0, treated surgically or with neoadjuvant or adjuvant therapy (i.e. chemotherapy, radiotherapy or chemoradiotherapy), or both.

Search methods

We searched the Cochrane Central Register of Controlled Trials (CENTRAL; 2019, Issue 6), along with OVID MEDLINE, six other databases and four trial registries with no language or date restrictions. We screened reference lists of relevant publications and handsearched meeting abstracts and conference proceedings of relevant organisations for additional relevant studies. All searches were completed between 6 June and 14 June 2019.

Selection criteria

We included randomised control trials (RCTs) and cluster-RCTs comparing physical activity interventions, to usual care or no physical activity intervention in adults with non-advanced colorectal cancer.

Data collection and analysis

Two review authors independently selected studies, performed the data extraction, assessed the risk of bias and rated the quality of the studies using GRADE criteria. We pooled data for meta-analyses by length of follow-up, reported as mean differences (MDs) or standardised mean differences (SMDs) using random-effects wherever possible, or the fixed-effect model, where appropriate. If a meta-analysis was not possible, we synthesised studies narratively.
Main results
We identified 16 RCTs, involving 992 participants; 524 were allocated to a physical activity intervention group and 468 to a usual care control group. The mean age of participants ranged between 51 and 69 years. Ten studies included participants who had finished active treatment, two studies included participants who were receiving active treatment, two studies included both those receiving and finished active treatment. It was unclear whether participants were receiving or finished treatment in two studies. Type, setting and duration of physical activity intervention varied between trials. Three studies opted for supervised interventions, five for home-based self-directed interventions and seven studies opted for a combination of supervised and self-directed programmes. One study did not report the intervention setting. The most common intervention duration was 12 weeks (7 studies). Type of physical activity included walking, cycling, resistance exercise, yoga and core stabilisation exercise.

Most of the uncertainty in judging study bias came from a lack of clarity around allocation concealment and blinding of outcome assessors. Blinding of participants and personnel was not possible. The quality of the evidence ranged from very low to moderate overall. We did not pool physical function results at immediate-term follow-up due to considerable variation in results and inconsistency of direction of effect. We are uncertain whether physical activity interventions improve physical function compared with usual care. We found no evidence of effect of physical activity interventions on disease-related mental health (anxiety: SMD -0.11, 95% confidence interval (CI) -0.40 to 0.18; 4 studies, 198 participants; I² = 0%; and depression: SMD -0.21, 95% CI -0.50 to 0.08; 4 studies, 198 participants; I² = 0%; moderate-quality evidence) at short- or medium-term follow-up. Seven studies reported on adverse events. We did not pool adverse events due to inconsistency in reporting and measurement. We found no evidence of serious adverse events in the intervention or usual care groups. Minor adverse events, such as neck, back and muscle pain were most commonly reported. No studies reported on overall survival or recurrence-free survival and no studies assessed outcomes at long-term follow-up.

We found evidence of positive effects of physical activity interventions on the aerobic fitness component of physical fitness (SMD 0.82, 95% CI 0.34 to 1.29; 7 studies, 295; I² = 68%; low-quality evidence), cancer-related fatigue (MD 2.16, 95% CI 0.18 to 4.15; 6 studies, 230 participants; I² = 18%; low-quality evidence) and health-related quality of life (SMD 0.36, 95% CI 0.10 to 0.62; 6 studies, 230 participants; I² = 0%; moderate-quality evidence) at immediate-term follow-up. These positive effects were also observed at short-term follow-up but not medium-term follow-up. Only three studies reported medium-term follow-up for cancer-related fatigue and health-related quality of life.

Authors’ conclusions
The findings of this review should be interpreted with caution due to the low number of studies included and the quality of the evidence. We are uncertain whether physical activity interventions improve physical function. Physical activity interventions may have no effect on disease-related mental health. Physical activity interventions may be beneficial for aerobic fitness, cancer-related fatigue and health-related quality of life up to six months follow-up. Where reported, adverse events were generally minor. Adequately powered RCTs of high methodological quality with longer-term follow-up are required to assess the effect of physical activity interventions on the disease-related physical and mental health and on survival of people with non-advanced colorectal cancer. Adverse events should be adequately reported.

Plain Language Summary
Physical activity interventions for the physical and mental health of people during and after treatment for bowel cancer

Background
Bowel cancer is the third most common cancer diagnosed worldwide. Being diagnosed and receiving treatment for bowel cancer can have a negative impact on a person’s physical and mental health. Side effects include reduced fitness levels and increased tiredness. People are also at risk of their cancer returning after treatment and this can cause fear and worry. Research on physical activity programmes in other cancer populations has shown benefits in reducing side effects of treatment. Given that people who are active have a lower chance of developing bowel cancer, physical activity may be beneficial for those with a bowel cancer diagnosis, but the research is not yet clear.

Review question
This review was undertaken to find out whether physical activity programmes are beneficial for the physical and mental health of people with bowel cancer and whether they are safe.

Key results
We found 16 studies that included 992 participants, our evidence is current to June 2019. Participants were randomly assigned to receive a physical activity programme or usual care (no physical activity programme). In the included studies, we are unsure whether physical activity programmes improve physical function and we found no effect of physical activity programmes compared to usual care on disease-related mental health. No serious adverse events occurred in the eight studies that looked at adverse events. There was inconsistency in reporting and measurement of adverse events. We do not know whether physical activity improves survival at any time point as no studies looked at this. The included studies suggest physical activity programmes may increase aerobic fitness, health-related quality of life (general well-being) and reduce fatigue (tiredness) in the short term. We are unsure of the long-term effects of physical activity interventions on physical function, disease-related mental health, adverse events, physical fitness, fatigue (tiredness), weight, health-related quality of life (general well-being) and physical activity levels because no studies assessed this.
Quality of the evidence
We rated the quality of the evidence from very low to moderate mainly because of the small number of studies and low number of participants, as well as study limitations.

Conclusion
The findings of this review should be interpreted with caution due to the low number of studies included and the quality of the evidence. This review shows the need for future high quality research with longer-term follow-up to assess the effects of physical activity interventions on the physical and mental health of people with bowel cancer, especially in relation to safety and survival.
### SUMMARY OF FINDINGS

#### Summary of findings 1. Physical activity compared with usual care in adults with non-advanced colorectal cancer

**Population:** adults with non-advanced colorectal cancer treated surgically or with neoadjuvant or adjuvant therapy, or both

**Settings:** all but one study undertaken in high-income countries. Included home-based self-directed and supervised physical activity programmes

**Intervention:** aerobic or resistance training, flexibility or balance training or a combination of these, lasting at least 4 weeks

**Comparison:** control intervention (usual care or no physical activity intervention)

**CES-D:** Centre for Epidemiological Studies Depression Scale; **CI:** confidence interval; **FACIT-F:** Functional Assessment of Chronic Illness Therapy-Fatigue; **FACT-C:** Functional Assessment of Cancer Therapy-Colorectal; **FACT-F:** Functional Assessment of Cancer Therapy-Fatigue; **FACT-G:** Functional Assessment of Cancer Therapy-General; **HADS:** Hospital Anxiety and Depression Scale; **HRQoL:** health-related quality of life; **MID:** Minimal important difference; **MD:** mean difference; **RCT:** randomised controlled trial; **SD:** standard deviation; **SMD:** standardised mean difference (used when studies assess the same outcome but measure it in a variety of ways).
Analysed with SMD and back estimated to MD to enable interpretation. SD for performing the calculation was obtained from study by Cramer 2016.
BACKGROUND

Description of the condition

Colorectal cancer is the third most commonly diagnosed cancer and the second leading cause of cancer death worldwide, accounting for an estimated 881,000 deaths in 2018 (GLOBOCAN 2018). Incidence and mortality rates vary globally, with higher incidence and lower mortality rates in higher-income countries (Arnold 2017; GLOBOCAN 2018; Stewart 2014). In general, incidence is higher in men than women and is strongly linked with age, with highest incidence among people aged 65 to 74 years (Howlader 2016). Incidence is currently stabilising in high-income countries, however a two-fold cumulative increase in incidence is expected by 2025, due to increasing incidence in low- to middle-income countries. With development, comes the adoption of more inactive lifestyles and unhealthy dietary habits; established risk factors for colorectal cancer (Stewart 2014). This is expected to increase the global burden of colorectal cancer, which may be compounded by a lack of health service resources in low- and middle-income countries to deal with the escalation in incidence (Stewart 2014).

Five-year survival from colon and rectal cancer has reached 60% or more in 22 countries worldwide (Allemani 2015). Between 1989 and 2011, colorectal cancer mortality rates decreased by more than 25% and 30% in men and women, respectively in high-income countries in Northern and Western Europe, but increased in most Eastern European countries (Ouakrim 2015). Similar trends are evident globally, with decreasing mortality rates in high-income countries, including Australia, Canada (Coleman 2011), the USA (Ryerson 2016), and Japan (Arnold 2017), and contrasting increasing mortality rates in low- and middle-income regions, such as Latin America and the Phillipines (Arnold 2017). These disparities are not easily explained and are likely due to differences in access to diagnostic and treatment services (Haggar 2009), with advancements in treatment and early detection contributing to decreasing mortality in high-income countries (Coleman 2011; Stewart 2014).

Although treatments are advancing, anti-cancer therapies are associated with a range of adverse physiological and psychological side effects, which affect morbidity and mortality (Devlin 2016a). Surgical resection is the primary treatment modality for stage I-III (T1-4 N0-2 M0) colorectal cancer, with systemic chemotherapy or radiotherapy (more often in rectal cancer), or both, given either in the adjuvant or neoadjuvant setting in stage III and high risk stage II patients (El-Shami 2015; Labianca 2010). Major abdominal surgery alone has been associated with declines in physical function (Schoeder 1991), and fatigue (Christensen 1982). Cancer-related fatigue affects between 60% to 96% of people with cancer during and following chemotherapy, radiotherapy or surgery (Cramp 2012; Thomas 2014; Wagner 2004). It is a distressing symptom defined as a sense of "physical tiredness or exhaustion related to cancer or cancer treatment" (NCCN 2016), which can interfere with one’s ability to carry out daily activities (Curt 2000), and negatively affect mood and quality of life (Stone 2008). Cancer-related fatigue is present in some colorectal cancer survivors at four years following diagnosis (Schneider 2007). Physical inactivity has been identified as both a risk factor for (Bower 2014), and a consequence of (Lynch 2010) cancer-related fatigue.

Declines in cardiorespiratory fitness can occur following treatment for colorectal cancer (Devlin 2016a; West 2014a). Lower levels of cardiorespiratory fitness are linked with higher rates of cancer-specific morbidity and mortality (Peel 2009; Schmid 2015), and can predict morbidity after colonic and rectal surgery (West 2014b; West 2014c). Furthermore, people with colorectal cancer may be susceptible to sarcopenia obesity (obesity with depleted muscle mass), which is associated with poorer functional status and poorer survival rates (Prado 2008; Wang 2017). These adverse effects, alone or in combination can impact adversely on a patient’s quality of life and subsequent physical activity levels (Cramer 2014b). Colorectal cancer survivors are also at an increased risk of developing second colorectal cancers (Green 2002; Markle 2010), non-colorectal cancers (Birgisson 2005), and other comorbidities (Denlinger 2011).

Concerns surrounding recurrence are common, affecting over half of cancer patients at one year following diagnosis (Baker 2005). Even at five years following surgery for colorectal cancer, survivors have concerns surrounding recurrence (Custers 2016). A significant minority of colorectal cancer patients and longer-term survivors of colorectal cancer (2 or more years postdiagnosis) experience clinically meaningful levels of psychological distress, including symptoms of anxiety and depression or reduced mental well-being (Mosher 2016). Colorectal cancer survivors report high quality of life at five years or longer postdiagnosis, but have higher rates of depression than age-matched populations (Ramsey 2002). Psychological outcomes vary greatly in this population, poorer psychological outcomes have been linked with the presence of existing comorbidities (Lynch 2008; Ramsey 2002), worse general health (Yost 2008), and lower socioeconomic status (Ramsey 2002). Levels of anxiety and depression are reported to be higher in people who undergo surgery with adjuvant chemotherapy or radiotherapy compared with surgery alone (Pereira 2012).

Description of the intervention

Physical activity interventions were the focus of this review. Physical activity is defined as any bodily movement produced by contraction of skeletal muscle that results in energy expenditure above resting energy expenditure (ACSM 2009; Caspersen 1985). For the purpose of this review the term ‘physical activity interventions’ included ‘exercise interventions’. Exercise is a subset of physical activity that is planned, structured and repetitive, done to improve or maintain one, or more of the components of physical fitness (ACSM 2009; Caspersen 1985). Physical activity interventions may be less structured than exercise interventions and often focus on promoting the integration of activities into daily life (e.g. gardening, walking or active travel). Physical activity interventions may be self-directed or supervised by a healthcare professional. They can involve aerobic or resistance training, flexibility or balance training, or a combination of these, can take place in any setting and can be individual or group based, or both. No restrictions were made regarding frequency, intensity, time or type of physical activity intervention included. Interventions were included if they lasted a minimum of four weeks, this was to exclude studies on the acute effects of physical activity.

Physical activity interventions are not currently delivered as part of standard practice during or following treatment for colorectal cancer. Early postoperative mobilisation is, however, strongly recommended, as part of the Enhanced Recovery After Surgery (ERAS) guidelines following colorectal surgery, encouraging patients to be out of bed for two hours on the day of surgery and six hours per day, thereafter until discharge (Lassen ...
Physical activity interventions for disease-related physical and mental health during and following treatment in people with non-advanced colorectal cancer (Review)

Physical activity has been proposed as non-pharmacologic intervention to attenuate the negative physiologic and psychologic effects of treatment in people with cancer (Courneya 2007; Schmitz 2005). There is a growing body of evidence from Cochrane and non-Cochrane systematic reviews demonstrating the positive impact of physical activity both during and following cancer treatment (Galvao 2005; Knols 2005; Schmitz 2005; Speck 2010). Exercise training improves cardiopulmonary fitness and muscle strength (Schmitz 2005; Speck 2010), overall health-related quality of life (HRQoL) (Knols 2005; Mishra 2012a; Mishra 2012b), and cancer-related fatigue in the general cancer population during and following cancer treatment (Cramp 2012; Furmaniak 2016; Speck 2010), and physical functioning during treatment (Mishra 2012a). Through improved cardiopulmonary fitness and muscle strength, physical activity may help address the physical deconditioning associated with cancer treatments (Schmitz 2005; Speck 2010), and help manage cancer-related fatigue (Al-Majid 2009; Cramp 2012). Physical activity may also help the emotional and mental aspects of cancer-related fatigue (Al-Majid 2009; Cramp 2012). Benefits of exercise interventions on psychological well-being (Knols 2005), anxiety and depression show positive trends but the evidence is not consistent (Cramp 2012; Furmaniak 2016; Mishra 2012a).

Cardiorespiratory fitness has been highlighted as an independent predictor of cancer mortality risk. Higher cardiorespiratory fitness is associated with a significant reduction in total cancer mortality (Schmid 2015), and colorectal cancer mortality (Peel 2009). Peel and colleagues report that men with at least a moderate fitness level had a 42% lower risk of colorectal mortality compared with men with a low cardiorespiratory fitness level. Evidence from observational studies suggest that physical activity is associated with overall and disease-free survival (Haydon 2006; Meyerhardt 2006; Meyerhardt 2009), in both colon and rectal cancer patients. There is consistent evidence linking physical activity to reduced colon cancer risk (Leitzmann 2015; Wolin 2009). A meta-analysis of 52 studies found an inverse association between physical activity and colon cancer, with an overall relative risk reduction of 24% (Wolin 2009). This is consistent with findings of an earlier meta-analysis of 19 cohort studies, which demonstrated a lower risk of colon cancer of 22% and 29% in physically active men and women, respectively (Samad 2005). Conversely, there appears to be no consistent association between physical activity and rectal cancer risk (Robsahm 2013).

The exact biological mechanisms for the observed benefit of physical activity for the prevention and secondary prevention of colorectal cancer are not fully understood. Various mechanisms have been proposed. Physical activity may reduce carcinogen exposure in the mucosa through decreased gastrointestinal transit time (Quadrilatero 2003; Slattery 2003), may alter prostaglandin levels (prostaglandins are unsaturated, free fatty acids that affect colon function) (Quadrilatero 2003), and may alter the insulin-like growth factor (IGF) pathway (Denlinger 2011; Fairey 2003). In people with colorectal cancer, moderate-intensity exercise has resulted in reduced levels of urinary markers of oxidative damage (Allgayer 2008), and decreased interleukin-1 receptor agonist (Allgayer 2004a), which may enhance immune function. Oxidative DNA damage is thought to be involved in tumour formation and may be associated with malignant transition and recurrence (Allgayer 2008). IGF-1 is important for cellular proliferation and survival (Hursting 2010), higher levels of which may be associated with increased risk of colorectal cancer (Giovannucci 2000), but this association remains elusive. Decreases in IGF and increases in IGF-binding proteins have been observed following exercise training in breast cancer survivors, which may be clinically relevant for the colorectal cancer population (Fairey 2003).

Physical activity may therefore be potentially effective in improving overall and recurrence-free survival. Indeed, given that regular physical activity can decrease the risk of colon cancer and has improved cardiopulmonary fitness, muscle strength, HRQoL and cancer-related fatigue in other cancer populations, it may be of clinical relevance for the colorectal cancer control continuum.

Why it is important to do this review

Colorectal cancer is a major public health problem. With the projected increasing incidence of colorectal cancer in low- and middle-income regions, increasing mortality rates in low- and middle-income countries and 3.5 million colorectal cancer survivors worldwide (Stewart 2014), there is a need to develop effective interventions that aid physical and psychological recovery, help alleviate treatment side effects and increase overall and recurrence-free survival. The Lancet Oncology commission has prioritised the reduction in morbidity and mortality associated with cancer, with a focus on "less toxic", "cost-effective" interventions (Sullivan 2011). There is, therefore, a need for a greater understanding of the effects of physical activity interventions on the disease-related physical and mental health of individuals with colorectal cancer, for policy, practice and for consumers.

To date, there are currently two published, non-Cochrane systematic reviews on exercise interventions for people with colorectal cancer (Cramer 2014b; van Rooijen 2018). In the review by Cramer 2014b no recommendations regarding exercise as a routine intervention for people with colorectal cancer were prioritised as other factors requiring attention of Sport and Exercise Science (BASES 2011) guidelines confirm that exercise can be safely performed during and following cancer treatment in the general cancer population. Specific guidance statements on physical activity interventions during and following treatment for colorectal cancer have not yet been published, due to lack of evidence on adverse effects and lack of safety data (Schmitz 2010). Side effects of treatments (cancer-related fatigue, pain, peripheral neuropathy, immune suppression, digestion issues, bowel dysfunction (including faecal incontinence) and urinary incontinence) may increase the risk of adverse events during physical activity. These side effects may represent barriers to physical activity participation (Denlinger 2009; Denlinger 2011; Rock 2012; Schmitz 2010). Indeed, chronic diarrhea is a side effect that has been associated with limitations in activity and negative body image (Schneider 2007). The presence of a stoma is also associated with diminished body image (Hong 2014). These side effects have been highlighted as factors to consider when prescribing physical activity. Existing comorbidities (most commonly cardiovascular disease, musculoskeletal problems and lung or breathing problems), particularly in older people with colorectal cancer have been highlighted as other factors requiring consideration, to reduce the risk of injury and adverse events (Denlinger 2009; Rock 2012; Schmitz 2010).

How the intervention might work

Physical activity has been proposed as non-pharmacologic intervention to attenuate the negative physiologic and psychologic effects of treatment in people with cancer (Courneya 2007; Schmitz 2005). There is a growing body of evidence from Cochrane and non-Cochrane systematic reviews demonstrating the positive impact of physical activity both during and following cancer treatment (Galvao 2005; Knols 2005; Schmitz 2005; Speck 2010). Exercise training improves cardiorespiratory fitness and muscle strength (Schmitz 2005; Speck 2010), overall health-related quality of life (HRQoL) (Knols 2005; Mishra 2012a; Mishra 2012b), and cancer-related fatigue in the general cancer population during and following cancer treatment (Cramp 2012; Furmaniak 2016; Speck 2010), and physical functioning during treatment (Mishra 2012a). Through improved cardiopulmonary fitness and muscle strength, physical activity may help address the physical deconditioning associated with cancer treatments (Schmitz 2005; Speck 2010), and help manage cancer-related fatigue (Al-Majid 2009; Cramp 2012). Physical activity may also help the emotional and mental aspects of cancer-related fatigue (Al-Majid 2009; Cramp 2012). Benefits of exercise interventions on psychological well-being (Knols 2005), anxiety and depression show positive trends but the evidence is not consistent (Cramp 2012; Furmaniak 2016; Mishra 2012a).
made due to insufficient evidence and lack of safety data. The review undertaken by Cramer and colleagues was limited to individuals who had completed treatment. The second review by van Rooijen and colleagues was undertaken in participants undergoing treatment, and highlighted the limited evidence of exercise training during treatment for colorectal cancer. Six out of seven studies included mixed-cancer populations, three of these studies were not RCTs. This review is restricted to RCTs only and includes individuals who are receiving adjuvant therapy in addition to those who have finished treatment; no previous review has included such a population. This review will update current evidence and include emerging evidence in relation to physical activity interventions for individuals with colorectal cancer and so identify current evidence gaps.

**OBJECTIVES**

To assess the effectiveness and safety of physical activity interventions on the disease-related physical and mental health of individuals diagnosed with non-advanced colorectal cancer, staged as T1-4 N0-2 M0, treated surgically or with neoadjuvant or adjuvant therapy (i.e. chemotherapy, radiotherapy or chemoradiotherapy), or both.

**METHODS**

**Criteria for considering studies for this review**

**Types of studies**

We considered randomised control trials (RCTs) and cluster-RCTs comparing physical activity interventions to usual care or no physical activity intervention for inclusion in this review.

**Types of participants**

We included studies that evaluated the effect of physical activity interventions, on adults (aged 18 years or over), regardless of gender, diagnosed with non-advanced colorectal cancer, staged as T1-4 N0-2 M0, treated surgically or with neoadjuvant or adjuvant therapy (i.e. chemotherapy, radiotherapy, chemoradiotherapy), or both. We included studies that examined physical activity interventions delivered during adjuvant therapy, following adjuvant therapy or following surgery alone. We excluded studies that included participants with other cancer types (unless outcomes for colorectal cancer were reported separately), and studies that included participants who were more than five years postdiagnosis.

**Types of interventions**

We compared physical activity interventions separately to no physical activity intervention or to usual care. Participants in both the control and intervention arms received the same usual care. Physical activity sessions could take place in any setting, be supervised, self-directed or both, could be individual or group based, or a combination of both. Physical activity modalities could include aerobic or resistance training, flexibility and balance training or a combination of these. No restrictions were made regarding frequency, intensity, time or type of exercise or physical activity intervention. We only included studies with interventions that lasted a minimum of four weeks in duration, to exclude studies on the acute effects of physical activity. We excluded studies with a prehabilitation component. We included studies that provided health education materials or seminars only if the physical activity intervention was the main intervention in the study. We recorded specific details on the intervention according to the FITT-VP (frequency, intensity, time, type, volume, progression) principle (ACSM 2014). We classified physical activity intensity as mild, moderate or vigorous based on the rate of perceived exertion, heart rate or metabolic equivalents report (ACSM 2014), and used the author’s classification of mild, moderate, or vigorous when a quantitative measure was unavailable.

**Types of outcome measures**

We extracted information for the primary and secondary outcomes at all available time points. We sought to analyse overall survival and recurrence-free survival at 12 months, three years and five years. We analysed the other primary and secondary outcomes according to the length of follow-up: up to 12 weeks after baseline (immediate); more than 12 weeks but less than or equal to six months after baseline (short term); more than six months but less or equal to 12 months after baseline (medium term) and more than 12 months after baseline (long term).

**Primary outcomes**

1. Overall survival (time interval between enrolment in the study and death of the person from any cause)
2. Recurrence-free survival (time interval between date of enrolment in the study and the date when colorectal cancer recurs or another cancer occurs during the follow-up)
3. Physical fitness (e.g. cardiorespiratory endurance (6-minute walk test; 10-metre shuttle walk test; VO2 peak or muscle strength (dynamometry; 1 repetition maximum; 5 repetition maximum) or another valid instrument)
4. Cancer-related fatigue (e.g. Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F); Schwartz Cancer Fatigue Scale (SCFS); Brief Fatigue Inventory (BFI); Piper Fatigue Scale (PFS))
5. Anthropometric measurements (e.g. weight, body mass index (BMI), body composition, waist measurement, skin-fold measurement)
6. HRQoL (e.g. European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30); Medical Outcomes Study Short Form-36 General Health Survey (SF-36); Functional Assessment of Cancer Therapy–Colorectal scale (FACT-C))

**Levels of physical activity (e.g. physical activity questionnaires (International Physical Activity Questionnaire (IPAQ), Global Physical Activity Questionnaire (GPAQ) or objective measures of physical activity using pedometers or accelerometers)
Search methods for identification of studies

Electronic searches
We searched the following electronic databases between 6 June 2019 and 14 June 2019 up to the latest issue, with no language or date restrictions to identify relevant RCTs and cluster-RCTs for this review.

1. The Cochrane Central Register of Controlled Trials (CENTRAL, in the Cochrane Library) (Appendix 1) (inception to present)
2. Ovid MEDLINE(R) Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Ovid MEDLINE(R) Daily and Ovid MEDLINE(R) (1946 to present) (Appendix 2)
3. Ovid Embase (1974 to present) (Appendix 3)
4. CINAHL (in EBSCOhost 1982 to present)
5. Web of Science (1970 to present)
6. PsycINFO (1806 to present)
7. Open Grey (formerly SIGLE) (1980 to present)
8. PEDro (1999 to present)

The searches were conducted by Cochrane Colorectal Cancer’s Information Specialist and a review author (MAT).

Searching other resources
We searched clinical trials registries separately on 6 June 2019 for ongoing studies and study protocols of:

1. Clinical.trials.gov (www.clinicaltrials.gov);
2. the World Health Organization International Clinical Trials Registry Platform (WHO ICTRP) (apps.who.int/trialsearch/);
3. the EU Clinical Trials Register (www.clinicaltrialsregister.eu/); and

We screened reference lists of all included studies and any relevant systematic reviews identified. We handsearched conference and meeting abstracts of relevant organisations including:

1. American Society of Clinical Oncology (ASCO);
2. European Society for Medical Oncology (ESMO);
3. American College of Sports Medicine (ACSM);
4. BIT’s Annual World Cancer Congress;
5. European Multidisciplinary Colorectal Cancer Congress (EMCCC);
6. European Federation for Colorectal Cancer (EFR); and
7. European Cancer Congress (ECC).

We contacted individuals or organisations for information on unpublished or ongoing studies.

Data extraction and management

Assessment of risk of bias in included studies
Two review authors (MMG and MAT) independently assessed each included study for risk of bias using the Cochrane ‘Risk of bias’ tool (Cochrane Handbook for Systematic Reviews of Interventions, Chapter 8.5.d, Higgins 2011a; Higgins 2017; Appendix 4). We assessed random sequence generation, allocation concealment, blinding of personnel and outcome assessment, completeness of outcome data, selective outcome reporting, and any other sources of bias, and judged the risk of bias as ‘high’, ‘low’ or ‘unclear’. We resolved any disagreements through discussion and where necessary, through involving a third review author (CC or MMC). For each study, we detailed the risk of bias in table form alongside a statement of justification for our judgement. We summarised results in both a 'Risk of bias' summary figure and 'Risk of bias' graph. When interpreting treatment effects, we took into account the risk of bias for studies that contribute to that outcome.

Measures of treatment effect
For continuous outcomes (physical function, disease-related mental health, physical fitness, cancer-related fatigue, anthropometric measurements, levels of physical activity and HRQoL) we determined the mean differences (MDs) or standardised
mean differences (SMDs) (in cases where different instruments were used to measure the selected outcome), in the intervention group compared with the control with 95% confidence intervals (CIs). We extracted data for final scores and change from baseline scores, if available.

In this version of the review, no outcomes were reported as time-to-event and we were unable to report adverse events as a dichotomous outcome. In future versions of this review for time-to-event outcomes (overall survival and recurrence-free survival) we will extract hazard ratios (HRs) with standard errors, assuming that the HR is constant over time to compare the risk of death or recurrence of cancer in the treatment group with that in the control group. Where HRs are not presented, we will estimate them from reported data (e.g. Kaplan-Meier curves, logrank observed minus expected events and the logrank variance) using methods described by Tierney and colleagues (Tierney 2007). For adverse events, we will calculate the risk ratio (RR) at individual study level by dividing the risk of an event in the intervention group by the risk of the event in the control group. We will define RRs greater than 1.0 as favouring the control group (i.e. fewer adverse events in the control group) and RRs less than 1.0 as favouring the intervention group (Deeks 2017).

**Unit of analysis issues**

For parallel-group, individually randomised trials, the colorectal cancer participant was the unit of analysis in each study. No cluster-RCTs met our inclusion criteria.

For studies reporting multiple follow-up time points, we conducted separate meta-analyses to reflect immediate-, short-, medium- and long-term periods of follow-up. For immediate-term follow-up we extracted data closest to the 12-week follow-up time point. For short- and medium-term follow-up, we extracted data closest to the six- and 12-month follow-up time point. For long-term follow-up, we extracted the longest time interval.

For studies with multiple arms, we included only relevant intervention arms. We combined all relevant intervention arms into a single group and combined all relevant control arms into a single group, creating a single, pair-wise comparison.

For future versions of this review, we will extract data from cluster-RCTs when they report appropriate analyses, adjusting for the sample size in each cluster. Where control of clustering has not been performed we will attempt to correct for the intervention effects of cluster-RCTs by reducing the size of each study to its 'effective sample size', which is the number of the original sample size divided by the 'design effect'. We will calculate the design effect as $1 + (M-1)*ICD$, where $M$ is the average cluster size and ICC is the intracluster correlation coefficient as described in the Cochrane Handbook for Systematic Reviews of Interventions, section 16.3.4 (Higgins 2011b). We will use an estimate of the ICC derived from the study (if possible), from a similar study or from a study of a similar population. If we use ICCs from other sources, we will report this and conduct sensitivity analyses to investigate the effect of variation in the ICC. If we identify both cluster-randomised trials and individually-randomised trials, we plan to synthesise the relevant information. We will consider it reasonable to combine the results from both if there is little heterogeneity between the study designs and the interaction between the effect of intervention and the choice of randomisation unit is considered unlikely.

**Dealing with missing data**

We attempted to contact authors of the included studies to request missing data on outcomes, participants and summary data via email. We documented reasons for missing data (missing at random or missing not at random) and how they were addressed. We assessed the extent to which studies analysed data according to the intention-to-treat principle. We assessed the level of missing data for included studies by comparing the number of participants included in the final analysis with the proportion of all participants in each study available in Characteristics of included studies. In future versions of this review, for studies at high risk of attrition bias, we will attempt to perform both the best-case and worst-case sensitivity analyses to assess the impact of missing data on the estimates of effect.

**Assessment of heterogeneity**

We evaluated clinical heterogeneity by examining diversity in participant characteristics, physical activity intervention characteristics, colorectal cancer treatment and outcomes among studies. We evaluated methodological heterogeneity by examining diversity in study designs and risk of bias. We did not pool methodologically heterogeneous studies. We visually inspected forest plots and used the Chi² test to assess statistical heterogeneity (with $P < 0.1$). We used the I² statistic to assess the percentage of variation across studies that is due to heterogeneity and not due to chance (Higgins 2003). We tentatively regarded heterogeneity as 'low' if $I^2$ is less than 49%, 'moderate', if $I^2$ is between 50% and 75% and 'high' if $I^2$ is more than 75% (Deeks 2017). We investigated potential sources of statistical heterogeneity by reassessing diversity in characteristics of studies (participant, intervention, treatment and outcomes) and by means of sensitivity analysis.

**Assessment of reporting biases**

We attempted to control for time-lag bias, location bias, citation bias and language bias by using a comprehensive search strategy without language or date restriction, that included searching for unpublished studies and searching trials registers. We controlled for multiple publication bias by identifying duplicate publications of the same study and grouping these together, listing them as one study. For studies published after 1 July 2005, we screened the Clinical Trials Register at the WHO ICTRP for the study protocols (apps.who.int/trialsearch) to evaluate whether selective reporting of outcomes was present (outcome reporting bias).

No analysis in this version of the review included more than 10 studies. For future versions of this review, if there are at least 10 studies included in a meta-analysis, we will visually inspect funnel plots for asymmetry to investigate potential publication bias or small-study effects following the recommendations in Chapter 10 of the Cochrane Handbook for Systematic Reviews of Interventions for any statistical testing of funnel plot asymmetry (Sterne 2017).

**Data synthesis**

We pooled results from comparable groups of studies using both fixed-effect and random-effects models, when appropriate. Whenever possible, we used a random-effects model with inverse variance weighting for meta-analyses (DerSimonian 1986), due to the nature of physical activity as a highly varied intervention. We used a fixed-effect model when there were few studies or if
the studies were small with few events. Where appropriate, we conducted a sensitivity analysis to investigate the effect of the choice of model (fixed-effect or random-effects) on the pooled estimate. MMG and CC conducted statistical analysis using RevMan 5 (Review Manager 2014). We considered a two-sided P value of less than 0.05 as statistically significant. In cases where measurement tools for outcomes had the opposite direction of effect, we multiplied mean scores of a selected measurement by minus one to ensure all scales had the same direction of effect as discussed in the Cochrane Handbook for Systematic Reviews of Interventions section, 9.2.3.2 (Deeks 2017). Where data aggregation was not possible due to heterogeneity, we provided a narrative synthesis of study results. We summarised the findings of the systematic review alongside an assessment of the quality of evidence for each individual outcome using the GRADE approach (GRADE Working Group 2004).

Subgroup analysis and investigation of heterogeneity

No subgroup analyses were conducted in this version of the review due to insufficient data or inclusion of a range of treatment stages, treatment types, participant ages, gender in each individual study, or both. In future versions of this review where there are sufficient data, we will perform subgroup analyses of the effect of the intervention according to:

1. exercise and physical activity intervention characteristics (using frequency, intensity, time, type, volume progression (FITT-VP) to calculate metabolic equivalents/hours per week);
2. participant characteristics (gender, age - over 65 years or under 65 years);
3. cancer stage (T1-2, N0, M0), (T3-4, N0, M0), (T1-4, N1-2, M0);
4. cancer type (colon or rectal);
5. treatment stage (during or post-treatment);
6. treatment type (laparoscopic or open surgery, neoadjuvant therapy or no neoadjuvant therapy);
7. time since diagnosis (zero to one year, two to three years, four to five years).

Sensitivity analysis

We undertook sensitivity analyses to assess the robustness of results. We reanalysed data after excluding studies with high risk of bias, those that had co-interventions (when appropriate) and studies that had not performed an intention-to-treat analysis. We conducted a sensitivity analysis to investigate heterogeneous results with the identification and removal of heterogeneous studies. We conducted a sensitivity analysis to investigate the effect of the choice of model (fixed-effect or random-effects) on the pooled estimate. In future versions of this review, for studies at high risk of attrition bias, we will conduct a best-case/worst-case sensitivity analysis to assess the impact of missing data on the estimates of effect. If there are any assumptions for ICC value used in cluster-RCTs, we will perform a sensitivity analysis.

Summary of findings

We assessed the overall quality of evidence of the main review outcomes using the GRADE approach in 'Summary of findings' (GRADE Working Group 2004). The 'Summary of findings' table highlights the overall quality of the body of evidence for the main review outcomes, using the GRADE criteria (study limitations (i.e. risk of bias), consistency of effect, indirectness, imprecision and publication bias). We used GRADEpro GDT 2015 software to prepare the 'Summary of findings' table. We will also present the results from the prespecified Sensitivity analysis and Subgroup analysis and investigation of heterogeneity when appropriate in 'Summary of findings' tables.

RESULTS

Description of studies

Results of the search

See: Characteristics of included studies; Characteristics of excluded studies; Characteristics of studies awaiting classification; Characteristics of ongoing studies

We conducted the comprehensive database search between 6 June 2019 and 14 June 2019 and found 5061 records. We identified 1092 additional records upon searching clinical trial registries and handsearching references lists, conference and meeting abstracts. After removing duplicates, 3837 potential records remained. We excluded a total of 3640 records based on the title and abstract and retrieved 197 records for more detailed evaluation (Figure 1).
Figure 1. PRISMA flow diagram.

- 5051 records identified through database searching
- 1. The Cochrane Central Register of Controlled Trials (CENTRAL, in the Cochrane Library) = 704
- 2. Ovid MEDLINE(R) = 410
- 3. Ovid Embase = 1001
- 4. CINAHL = 468
- 5. Web of Science = 2353
- 6. PsycINFO = 107
- 7. OpenGrey (formerly SIGLE) = 5
- 8. PEDro = 73
- 1092 additional records identified through other sources
- 3837 records after duplicates removed
- 197 records remaining after screening by title and then abstract
- 3540 records excluded
- 99 trials (127 records - full-text articles) excluded, with reasons
- 9 ongoing trials (9 records)
- 15 trials (31 records) awaiting classification
- 197 full-text records assessed for eligibility
- 16 studies (40 records) included in qualitative synthesis
From these, we excluded 99 studies (127 records) as they did not meet the inclusion criteria (see 'Characteristics of excluded studies') and 16 studies (40 records) were appropriate for inclusion in the current review. In addition, nine studies are ongoing and 15 studies (21 records) are awaiting classification; we did not include these studies in the analysis presented below, but will consider them in future updates of this review. We completed all searches by 14 June 2019. Figure 1 illustrates the process of the literature search and study selection for the review based on the PRISMA template (Moher 2009).

Included studies

We included 16 studies in this review (14 journal articles and 2 dissertations) (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Courneya 2016; Cramer 2016; Hubbard 2016; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Pinto 2013; Van Blarigan 2019; Van Vulpen 2016; Waart 2017). We used the main publication as the study reference. We reviewed and included information on study characteristics and outcome related data from an additional 28 publications that were secondary publications of seven of these 16 studies. We contacted 11 study authors for additional information (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Cramer 2016; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Van Vulpen 2016; Waart 2017), eight of these authors replied to information requests (Bourke 2011; Courneya 2003; Cramer 2016; Lewis 2016; McDermott 2017; Nuri 2016; Van Vulpen 2016; Waart 2017). For study characteristics and outcomes, see the Characteristics of included studies table.

Study characteristics

All 16 included studies were randomised controlled trials (RCTs). No cluster-RCTs met our inclusion criteria. All studies except for two randomised participants to either a physical activity or usual care arm (Brown 2017; Waart 2017). These two studies included an additional study arm, that included variations in exercise volume in Brown 2017 and exercise intensity in Waart 2017. Three studies included co-interventions (Bourke 2011; Courneya 2016; Hubbard 2016), involving healthy eating seminars and a dietary information pack (Bourke 2011), health education materials for the usual care group (Courneya 2016), and weekly education sessions on topics, including physical activity, diet stress management and cardiac specific issues (Hubbard 2016). In all, investigators allocated 992 participants (mean 62, range 18 to 273) to a physical activity intervention group (n = 524, mean 33, range 9 to 136) or a control group (n = 468, mean 29, range 9 to 137).

Participants

Participants enrolled in the studies had a diagnosis of colon or colorectal cancer, six studies included only participants with colon cancer (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2016; Van Vulpen 2016; Waart 2017), whilst the remaining 10 studies included participants with colorectal cancer (Courneya 2003; Cramer 2016; Hubbard 2016; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Pinto 2013; Van Blarigan 2019). Four studies reported the percentage of rectal cancer participants included (Kim 2018; McDermott 2017; Pinto 2013; Van Blarigan 2019). No studies with exclusively rectal cancer participants met our inclusion criteria. The majority of studies included participants with stage I-III colorectal cancer, however Courneya 2016, Lee 2017 and Waart 2017 excluded participants with stage I cancer. In addition, Waart 2017, Courneya 2003 and Van Blarigan 2019 included a minority of participants with stage IV cancer, when contacted Waart 2017 confirmed that no stage IV participants were included, Courneya 2003 was unable to provide separate data, excluding the four stage IV participants that were included in the study. Van Blarigan 2019 included one stage IV participant (2% of total participants included). Ten studies included participants who had finished active treatment (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2016; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Pinto 2013; Van Blarigan 2019), the time beyond treatment ranged between two months and five years. Two studies included participants receiving active treatment (Van Vulpen 2016; Waart 2017). Two studies were conducted among participants who were receiving and finished active treatment (Cramer 2016; Hubbard 2016). It was unclear whether participants were receiving or finished treatment in two studies (Courneya 2003; Nuri 2016). The majority of participants had undergone surgery as treatment; chemotherapy was also common across studies with less participants receiving radiotherapy. Mean time since diagnosis was only reported in six studies and ranged between 10 weeks and 2.99 years (Cantarero-Villanueva 2016; Courneya 2016; Lewis 2016; Pinto 2013; Van Blarigan 2019; Van Vulpen 2016). The mean age of participants ranged between 51 and 69 years. Fifteen studies included both males and females, with one study including only males (Nuri 2016). Comorbidities and ethnicity were largely unreported in studies. Only two studies reported comorbidities at baseline (Brown 2017; Waart 2017). Two studies reported on ethnicity of participants (Brown 2017; Pinto 2013), in both studies the majority of participants were white. Eight studies reported on education levels of participants (Cantarero-Villanueva 2016; Courneya 2003; Cramer 2016; Kim 2018; Lee 2017; Van Blarigan 2019; Van Vulpen 2016; Waart 2017) with Kim 2018, Lee 2017, Van Vulpen 2016 and Waart 2017 further reporting on marital status and McDermott 2017, Van Blarigan 2019 and Waart 2017.
reporting on employment status. Five studies reported recruiting those who were currently inactive (Bourke 2011; Courneya 2016; Lee 2017; Lewis 2016; McDermott 2017).

**Interventions**

Type and setting of interventions varied across studies. Three studies opted for exclusively supervised physical activity interventions (Cantarero-Villanueva 2016; Cramer 2016; Hubbard 2016), likely due to the modes of exercise which included hatha yoga, core stabilisation exercise and cardiac rehabilitation exercise classes. The settings for these interventions were not clearly reported. Five studies opted for exclusively home-based self-directed programmes (Brown 2017; Courneya 2003; McDermott 2017; Pinto 2013; Van Blarigan 2019), which consisted of mainly aerobic physical activity (e.g. treadmill walking, cycling). A combination of aerobic and resistance exercise was prescribed in two studies (McDermott 2017; Van Blarigan 2019). The Nuri 2016 study involved aerobic physical activity, whether the physical activity was supervised or self-directed is unclear. Seven studies opted for a combination of supervised and self-directed physical activity (Bourke 2011; Courneya 2016; Kim 2018; Lee 2017; Lewis 2016; Van Vulpen 2016; Waart 2017), with physical activity logs in Lee 2017 and telephone support in Courneya 2016 and Kim 2018. A combination of aerobic and resistance physical activity was conducted in four of these studies (Bourke 2011; Lee 2017; Van Vulpen 2016; Waart 2017), with Courneya 2016 encouraging activity based on individual preference, with a walking prescription if individuals had no preference.

The intensity of the physical activity varied slightly between studies. Methods used to measure intensity of the physical activity included relatively objective measures, such as percentage of maximum heart rate, heart rate at ventilatory threshold, percentage of predicted maximum workload and ratings of perceived exertion. The majority of studies opted for moderate-intensity physical activity (Bourke 2011; Brown 2017; Courneya 2003; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Pinto 2013; Waart 2017), with three studies incorporating vigorous physical activity (Lewis 2016; Van Blarigan 2019; Waart 2017). An arm of the Waart 2017 study participated in low-intensity exercise. Five studies did not report intensity of the physical activity programme (Cantarero-Villanueva 2016; Courneya 2016; Cramer 2016; Hubbard 2016; Kim 2018).

The most common duration of physical activity intervention was 12 weeks (Bourke 2011; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Pinto 2013; Van Blarigan 2019). In one study, the length of the intervention was determined by duration of chemotherapy, with participants beginning the intervention with the first cycle of chemotherapy and finishing three weeks after the last cycle (Waart 2017). For another study (Hubbard 2016), the length of intervention varied depending on hospital site (6, 10 or 12 weeks). Two studies delivered eight-week interventions (Cantarero-Villanueva 2016; Nuri 2016). The duration of the other five studies were 10 weeks (Cramer 2016), 16 weeks (Courneya 2003), 18 weeks (Van Vulpen 2016), six months (Brown 2017), and three years (Courneya 2016). However, the Courneya 2016 study is ongoing and we have extracted one-year interim data for this review. All studies conducted follow-up assessments on completion of the exercise intervention. Nine studies conducted a further set of equivalent assessments at a later time point (Cantarero-Villanueva 2016; Cramer 2016; Hubbard 2016; Lewis 2016; McDermott 2017; Nuri 2016; Pinto 2013; Van Vulpen 2016; Waart 2017). Pinto 2013 was the only study to conduct three postintervention assessments, these took place at three, six and 12 months.

**Control groups**

The control groups received usual care, were not prescribed physical activity and did not take part in any formal exercise training during the course of the intervention. Five studies provided participants with written information on maintaining a healthy lifestyle (Courneya 2016; Hubbard 2016; Pinto 2013; Van Blarigan 2019), or provided recommendations for a healthy lifestyle (Cantarero-Villanueva 2016). Three studies reported asking participants in the control arm to maintain their usual daily physical activity levels/lifestyle habits during the intervention (Brown 2017; Lee 2017; Van Vulpen 2016). One study instructed participants not to initiate any structured exercise over the course of the intervention (Courneya 2003). Three studies had a waiting list control group, providing participants the opportunity to take part in the physical activity intervention following completion of the study (Brown 2017; Cramer 2016; Lewis 2016). Van Blarigan 2019 offered a fit bit flex to control group participants following study completion. Pinto 2013 controlled for frequency of contact with participants by having a contact control group.

**Outcome measures**

The most frequently assessed outcome among the 16 included studies was physical fitness, measured in 12 studies (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Courneya 2016; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Pinto 2013; Van Vulpen 2016; Waart 2017), the most commonly used tools to measure physical fitness were the six-minute walk test (Brown 2017; Cantarero-Villanueva 2016; Courneya 2016; Lee 2017; Lewis 2016) and treadmill tests using a variety of protocols (Courneya 2003; Lewis 2016; Pinto 2013; Van Vulpen 2016; Waart 2017). Twelve studies measured levels of physical activity, objectively, using accelerometer data (Brown 2017; Hubbard 2016; Lewis 2016; McDermott 2017; Pinto 2013; Van Blarigan 2019), and subjectively, using a variety of self-report questionnaires (Bourke 2011; Courneya 2003; Courneya 2016; Kim 2018; Lee 2017; Lewis 2016; Pinto 2013; Waart 2017). Lewis 2016 and Pinto 2013 measured levels of physical activity, both objectively and subjectively. Ten studies assessed anthropometric measurements (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Courneya 2016; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Van Vulpen 2016). All studies except for Courneya 2003 measured weight and only two did not measure body mass index (BMI) (Courneya 2016; Van Vulpen 2016). Fatigue and health-related quality of life (HRQoL) were assessed in nine studies, out of the 16 included (Bourke 2011; Courneya 2003; Cramer 2016; Kim 2018; Lewis 2016; McDermott 2017; Pinto 2013; Van Vulpen 2016; Waart 2017), most frequently using the Functional Assessment of Cancer Therapy – Fatigue (FACT-F) scale and Functional Assessment of Cancer Therapy – Colorectal (FACT-C) scale, respectively. Adverse events were reported in eight studies, of these the absence of any adverse events were reported in four studies (Hubbard 2016; Lewis 2016; Van Vulpen 2016; Waart 2017), whilst four studies recorded the number of adverse events that occurred (Brown 2017; Cantarero-Villanueva 2016; Cramer 2016; Van Blarigan 2019). Six studies assessed facets of mental health and well-being (Courneya 2003; Cramer 2016; Kim 2018; McDermott 2017; Van Vulpen 2016; Waart 2017), mainly anxiety and depression, using the Hospital Anxiety...
and Depression Scale (HADS) score. Other outcomes including overall and recurrence-free survival were not reported in any of the included studies. Adherence to Enhanced Recovery After Surgery (ERAS) guidelines and length of hospital stay was not reported in any of the included studies. For detailed information on outcome measures, see the Characteristics of included studies table.

Excluded studies

We excluded 99 trials from the review due to the following reasons.

1. Wrong patient population (n = 19)
2. Wrong study design (n = 25)
3. Wrong comparator (n = 18)
4. Wrong intervention (n = 16)
5. Intervention too short (n = 10)
6. Did not analyse colorectal cancer patients separately (n = 8)
7. Study was not carried out (n = 2)
8. Outcomes were not relevant (n = 1)

See Characteristics of excluded studies for an overview.

Risk of bias in included studies

We assessed the risk of bias for each included study using the 'Risk of bias' assessment tool and recommendations for judging risk of bias provided in Chapter 8 of the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2017). See Figure 2 for an overall assessment of risk of bias presented as percentages across all included studies. In addition, Figure 3 provides a 'Risk of bias' summary for each included study. Due to the nature of the intervention, it was expected that blinding of participants and personnel delivering the interventions would not be possible. We therefore judged risk of performance bias as high in all included studies. See Characteristics of included studies.

**Allocation**

**Random sequence generation**

Twelve studies (75%) were at low risk of selection bias owing to adequate generation of a randomised sequence (Bourke 2011; Cantarero-Villanueva 2016; Courneya 2003; Cramer 2016; Hubbard 2016; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Van Blarigan 2019; Van Vulpen 2016; Waart 2017). We considered four studies to have an unclear risk of selection bias as they did not describe the generation of a randomised sequence (Brown 2017; Courneya 2016; Nuri 2016; Pinto 2013).

**Allocation concealment**

Five studies (36%) were at low risk of selection bias owing to adequate concealment of allocation, so that participants and investigators could not foresee assignment to the study groups.
(Cantarero-Villanueva 2016; Cramer 2016; Lewis 2016; McDermott 2017; Van Vulpen 2016). The other 11 studies were considered to have an unclear risk of selection bias owing to allocation concealment as they did not describe the method of concealment.

**Blinding**

**Blinding of participants and personnel**

Due to the nature of physical activity interventions, blinding of participants and personnel is not possible. Therefore, we judged all included studies at high risk of performance bias.

**Blinding of outcome assessors**

Six studies were at low risk of detection bias as outcome assessors were blinded to participants group assignment (Bourke 2011; Brown 2017; Courneya 2003; Cantarero-Villanueva 2016; Pinto 2013; Van Vulpen 2016). We considered seven studies to have unclear risk for detection bias, as blinding of outcome assessors was not described (Cantarero-Villanueva 2016; Cramer 2016; Hubbard 2016; Kim 2018; Lee 2017; Nuri 2016; Waart 2017). Three studies were at high risk for detection bias as the outcome assessor was aware of participants’ group allocation (Lewis 2016; McDermott 2017; Van Blarigan 2019).

**Incomplete outcome data**

All included studies reported on adherence. All studies except for Hubbard 2016 were at low risk of attrition bias due to the amount, nature or handling of incomplete outcome data. Hubbard 2016 was at high risk of attrition bias due to the amount of missing data. Adherence to physical activity interventions in other studies varied between 71% and 97%.

**Selective reporting**

Ten studies were at low risk of reporting bias (Bourke 2011; Courneya 2003; Courneya 2016; Cramer 2016; Kim 2018; Lee 2017; Lewis 2016; McDermott 2017; Pinto 2013; Van Vulpen 2016). Six studies were at high risk of reporting bias, as study protocols or methods sections included outcomes which were not reported in available publications (Brown 2017; Cantarero-Villanueva 2016; Hubbard 2016; Nuri 2016; Van Blarigan 2019; Waart 2017).

**Other potential sources of bias**

**Baseline imbalances**

Eleven studies were at low risk of selection bias owing to the absence of significant imbalances between group at baseline (Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Courneya 2016; Kim 2018; Lee 2017; Lewis 2016; Nuri 2016; Van Vulpen 2016), or in studies were baseline imbalances were present, appropriate allocation concealment was described (Cramer 2016; McDermott 2017). Four studies were at high risk of selection bias because group similarity at baseline was inadequate (Hubbard 2016; Pinto 2013; Van Blarigan 2019; Waart 2017). The risk of selection bias owing to baseline imbalances was unclear in one study as baseline imbalances were not reported (Bourke 2011). All included studies are at risk of participation bias, with the potential for the more motivated participants agreeing to participate.

**Effects of interventions**

See: **Summary of findings 1** Physical activity compared with usual care in adults with non-advanced colorectal cancer

All trial authors reported study results as follow-up values and six studies also included change in score from baseline to follow-up (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2016; Hubbard 2016; Lewis 2016). We completed meta-analyses for both types of outcomes separately and for each follow-up time period where data were available. We categorised follow-up as: up to 12 weeks after baseline (immediate); more than 12 weeks but less than or equal to six months after baseline (short term); more than six months but less than or equal to 12 months after baseline (medium term); and more than 12 months after baseline (long term). No included studies reported follow-up of greater than 12 months after baseline. One study reported follow-up time points to end of chemotherapy treatment and at six months following completion of chemotherapy treatment (Waart 2017). We calculated follow-up time points in months, using the reported percentage of chemotherapy treatment received. This was as a proportion of the average total planned duration of chemotherapy. Where studies had two intervention arms (Brown 2017; Waart 2017), or reported gender separately (Van Vulpen 2016), we combined these arms in RevMan to form a single pair-wise comparison (Review Manager 2014).

**Primary outcomes**

**Physical function**

A total of 10 studies reported on physical function, assessed using a variety of measures, including the 30-Second Chair Stand Test (Bourke 2011; Courneya 2016; Lee 2017; Lewis 2016; McDermott 2017), the Physical Functioning subscale of the Short Form-36 (SF-36) (Brown 2017; Pinto 2013), the functional well-being subscale of the Functional Assessment of Cancer Therapy-Colorectal (FACT-C; Courneya 2003), the physical function subscale of the European Organisation for Research and Treatment of Cancer Quality of life Questionnaire-Core 30 (EORTC QLQ-C30; Waart 2017), and the Trial Outcome Index-physical/functional/colorectal (Kim 2018). We conducted separate meta-analyses for objectively and subjectively measured physical function.

Four studies including 185 participants measured physical function using the 30-Second Chair Stand Test at immediate-term follow-up (Bourke 2011; Lee 2017; Lewis 2016; McDermott 2017), we did not pool these results in a meta-analysis due to considerable variation in results and inconsistency in direction of effect. Lewis 2016 and McDermott 2017 observed no difference between the physical activity and usual care groups for physical function at immediate-term follow-up, whilst, Bourke 2011 and Lee 2017 reported significant improvements in physical function in the physical activity group compared with usual care (P = 0.003 and P = 0.005, respectively). We observed no evidence of difference between groups at short-term follow-up when measured objectively (mean difference (MD) 0.76, 95% confidence interval (CI) -1.84 to 3.36; 2 studies, 39 participants; I² = 0%; moderate-quality evidence; Analysis 1.1; Figure 4), and subjectively at short-term follow-up (standardised mean difference (SMD) 0.09, 95% CI -0.24 to 0.42; 3 studies, 156 participants; I² = 0%; low-quality evidence; Analysis 1.2; Figure 5). There were insufficient data to analyse subjective and objective physical function at medium-term follow-up, subjective physical function at immediate-term follow-up, and change from baseline results at all four follow-up time points.
Figure 4. Forest plot of comparison: 1 Physical activity versus usual care for physical function (30-sec chair sit-to-stand test), outcome: 1.2 Objective measures more than 12 weeks to six months follow-up (short term).

Test for subgroup differences: Not applicable

Courneya 2016 reported that the structured exercise group (n = 99) improved relative to the health education material group (n = 98) for the 30-Second Chair Stand Test (mean between group difference (+1.6 repetitions; 95% Cl +0.6 to +2.7); P < 0.001) at one year. Pinto 2013 reported no significant group differences at immediate- or medium-term follow-up for self-reported physical functioning (n = 23 and n = 19 for physical activity and usual care, respectively). Brown 2017 reported improvements in change from baseline scores for physical function at short-term follow-up with higher doses of physical activity resulting in greater improvements. Kim 2018 reported no difference between groups at immediate-term follow-up for physical function (P = 0.254). However, change from baseline to immediate-term follow-up improved in the intervention group (mean 64.1 (11.2) versus 66.3 (11.8), P = 0.035).

We performed sensitivity analyses to investigate the choice of model on the pooled estimate at all included time points. Sensitivity analyses using a fixed-effect model were consistent with findings from a random-effects model. The sensitivity analysis revealed no difference in effect when we removed studies that did not use an intention-to-treat (ITT) analysis; this was only possible for subjective measures at short-term follow-up (Table 1).

Disease-related mental health

A total of seven studies reported on disease-related mental health, assessed by the Hospital Anxiety and Depression Scale (HADS) (Cramer 2016; Van Vulpen 2016; Waart 2017), the Positive and Negative Affect Scale (PANAS) (McDermott 2017), the State-Trait Anxiety Inventory (Courneya 2003), the Centre for Epidemiological Studies Depression Scale (CES-D) (Courneya 2003), and the Patient Health Questionnaire (Kim 2018). We obtained postintervention data and separate scores for anxiety and depression through email correspondence with authors Van Vulpen 2016 and Waart 2017, respectively. We conducted meta-analyses for anxiety and depression separately at 12 weeks to six months after baseline and more than six months to 12 months after baseline.

There was no evidence of difference in depression between the physical activity group and usual care group at short-term follow-up (SMD -0.21; 95% CI -0.50 to 0.08; 4 studies, 198 participants; I² = 0%; moderate-quality evidence; Analysis 2.1; Figure 6), or medium-term follow-up (assessed using HADS) (MD -1.20; 95% CI -2.72 to 0.31; 2 studies, 48 participants; I² = 32%; low-quality evidence; Analysis 2.2; Figure 7).
There was no evidence of difference in anxiety between the physical activity group and usual care group at short-term follow-up (SMD -0.11, 95% CI -0.40 to 0.18; 4 studies, 198 participants; I² = 0%; moderate-quality evidence; Analysis 2.3; Figure 8), or medium-term follow-up (assessed using HADS) (anxiety: MD 1.79, 95% CI -0.37 to 3.94; 2 studies, 47 participants; I² = 30%; low-quality evidence; Analysis 2.4; Figure 9). Data were insufficient for analysis of immediate-term follow-up and change scores at all four time points.
Eight out of the 16 included studies reported on adverse events (Brown 2017; Cantarero-Villanueva 2016; Cramer 2016; Hubbard 2016; Lewis 2016; Van Blarigan 2019; Van Vulpen 2016; Waart 2017). We did not pool adverse events due to inconsistency in reporting and measurement. Of the eight studies, four studies reported that no adverse events (Hubbard 2016; Lewis 2016; Waart 2017) or serious adverse events (Van Vulpen 2016) occurred during the study period. The method of measurement of adverse events was not described by authors, Van Vulpen 2016 and Waart 2017. Van Vulpen 2016 and Lewis 2016 did not make reference to ‘non-serious’ adverse events. Hubbard 2016 recorded adverse events in a participant log and recorded them as “related” or “unrelated” to the exercise intervention. In the study by Van Blarigan 2019 participants completed an online health check survey which recorded adverse events. Commonly reported non-serious adverse events included low back, knee, joint, muscle and chest pain, inflammation of joints in both the intervention (n = 39) and control (n = 36) groups.

We graded the evidence of the included studies as low quality (8 studies, 305 participants).

Secondary outcomes

Overall survival

No RCTs reported overall survival.

Recurrent-free survival

No RCTs reported recurrence-free survival as an outcome. No studies reported cancer recurrence as reasons for dropout. One study reported lung metastasis in the intervention group as a reason for dropout (Lewis 2016).

Physical fitness

Aerobic fitness

A total of 12 studies reported aerobic fitness, using a variety of different measures including: the six-minute walk test (Brown 2017; Cantarero-Villanueva 2016; Courneya 2016; Lee 2017; McDermott 2017), the Bruce Protocol Treadmill Test (Bourke 2011; Lewis 2016), the Modified Balke Treadmill Test (Courneya 2003), V0₂ peak test (Van Vulpen 2016); Cycle Ergometer Peak Power Output Test (Van Vulpen 2016), Rockport Walk Test (Nuri 2016), treadmill test (Pinto 2013), and the Steep Ramp Test (Waart 2017). Nuri 2016 and Pinto 2013 estimated V0₂ peak from submaximal fitness tests; we used this data in our meta-analysis. No included studies reported change from baseline data at more than 12 months follow-up.
At immediate-term follow-up, we observed an improvement in aerobic fitness in the physical activity group compared with the usual care group (SMD 0.82, 95% CI 0.34 to 1.29; 7 studies, 295 participants; $I^2 = 68\%$; low-quality evidence; Analysis 3.1). This effect was also observed at short-term follow-up (SMD 0.56, 95% CI 0.29 to 0.82; 7 studies, 248 participants; $I^2 = 1\%$; moderate-quality evidence; Analysis 3.3), but not at medium-term follow-up (SMD 0.44, 95% CI -0.04 to 0.92; 4 studies, 272 participants; $I^2 = 57\%$; very low-quality evidence; Analysis 3.5).

Change in aerobic fitness from baseline showed an improvement compared with usual care at immediate-term follow-up (SMD 0.89, 95% CI 0.43 to 1.36; 3 studies, 81 participants; $I^2 = 0\%$; low-quality evidence; Analysis 3.2) and short-term follow-up (SMD 0.62, 95% CI 0.05 to 1.19; 2 studies, 51 participants; $I^2 = 0\%$; moderate-quality evidence; Analysis 3.4). We were unable to include data from the study by Brown 2017 in the meta-analysis as the authors reported mean change between groups over time. We emailed to request postintervention and change from baseline data, but no reply was received.

We conducted a sensitivity analysis excluding studies with an additional component (dietary advice), studies that did not conduct an ITT analysis and those at high risk of bias; results suggest improvements in aerobic fitness in the physical activity group compared with usual care (SMD 0.38, CI 0.06 to 0.70; 4 studies, 207 participants; $I^2 = 15\%$; Table 1) at immediate-term follow-up and short-term follow-up (SMD 0.45, CI 0.15 to 0.75; 5 studies, 187 participants; $I^2 = 0\%$; Table 1). We also conducted a sensitivity analysis at medium-term follow-up excluding the study in which the physical activity intervention was ongoing. Results of this suggest no improvement in aerobic fitness in the physical activity group compared with usual care (SMD 0.44, CI 0.41 to 1.29; 3 studies, 86 participants).

**Upper body strength**

A total of five studies reported upper body strength, including arm strength, assessed by hand grip dynamometry (Lee 2017; Lewis 2016; Waart 2017), the 30 second arm-curl test (Lewis 2016; Courneya 2016), isometric abdominal strength and isometric back strength assessed by the trunk-curl test and back dynamometry, respectively (Cantarero-Villanueva 2016), and the push-up test to assess upper body strength and endurance (Lee 2017). A meta-analysis was conducted for hand grip strength only, due to the large variability in measurement of upper body strength. Data were insufficient for analysis of more than six months to 12 months follow-up and for change scores at all four time points.

We observed no difference in hand grip strength, assessed using hand grip dynamometry in the physical activity group compared with usual care at immediate-term follow-up (MD 1.92, 95% CI -1.17 to 5.00; 2 studies, 147 participants; $I^2 = 0\%$; low-quality evidence; Analysis 4.1) or at short-term follow-up (MD 0.94, 95% CI -5.98 to 7.87; 2 studies, 39 participants; $I^2 = 0\%$; very low-quality evidence; Analysis 4.2). In the study by Lee 2017, hand grip strength was reported separately for the left and right hand. We contacted Lee 2017 to request combined data, but we received no response. We inputted the data from the right hand only.

Lee 2017 reported a significantly greater improvement in the push-up test ($P < 0.001$) in the intervention group ($n = 62$) compared with control ($n = 61$) at 12 weeks. The physical activity group ($n = 21$) experienced a greater increase in isometric abdominal strength compared with that of the usual care group ($n = 19$) at eight weeks ($P = 0.001$) but not at six months follow-up in the study by Cantarero-Villanueva 2016. No significant difference was found between groups for isometric back strength. There were no significant group differences in change in arm-curl repetitions in the study by Lewis 2016 ($n = 12$ for the physical activity group and usual care group at 12 weeks; $n = 9$ and $n = 11$ at 6 months, respectively) or in the study by Courneya 2016 ($P = 0.18$) ($n = 99$ and $n = 98$ for the physical activity and usual care groups, respectively) at one year.

**Flexibility**

Three studies measured flexibility, assessed by the Sit and Reach Test (Courneya 2003; Courneya 2016), and the Modified Sit and Reach Test (Cantarero-Villanueva 2016). Cantarero-Villanueva 2016 reported flexibility of the right and left side separately. We emailed the author, but were unable to obtain combined sit and reach scores. We used data for the right side in our analysis. Mean scores were multiplied by minus one to ensure all scales had the same direction of effect as discussed in the Cochrane Handbook for Systematic Reviews of Interventions section, 9.2.3.2 (Deeks 2017). We observed no difference in flexibility in the physical activity group compared to usual care at short-term follow-up (SMD 0.02, 95% CI -0.36 to 0.39; 2 studies, 119 participants; $I^2 = 0\%$; low-quality evidence; Analysis 5.1). There were insufficient data for analysis of flexibility at immediate- and medium-term follow-up and for change scores at all four time points.

Courneya 2016 reported that the structured exercise group ($n = 99$) improved relative to the health education material group ($n = 98$) for the Sit and Reach Test (mean between group difference of +2.1 cm; 95% CI -0.6 to +4.7; $P = 0.08$) at one year.

**Lower limb strength**

Two studies measured lower body strength, using dynamometry to assess maximum voluntary torque production of the knee extensors (Bourke 2011; Waart 2017). Meta-analysis was precluded as studies measured lower limb strength at different time points. In the study by Bourke 2011, no difference in maximum voluntary torque was observed between the intervention ($n = 9$) and control group ($n = 9$) over the 12-week intervention period ($P = 0.127$). Conversely, Waart 2017 observed improvements in lower body strength in the usual care control group ($n = 6$), the onco-move group (low-intensity home-based exercise; $n = 6$) and a reduction in strength in the on-track intervention group (moderate- to high-intensity supervised exercise; $n = 7$) at the end of chemotherapy (calculated as 4.8 to 5 months follow-up). At six months following chemotherapy (calculated as 10 to 11 months follow-up), the on-track group ($n = 6$) recovered to above baseline values (no P values were reported).

**Cancer-related fatigue**

A total of 10 studies reported cancer-related fatigue, assessed by the Functional Assessment of Chronic Illness Therapy - Fatigue (FACT-F) (Cramer 2016; Kim 2018; McDermott 2017), the Functional Assessment of Cancer Therapy - Fatigue (FACT-F) (Bourke 2011; Courneya 2003; Lewis 2016; Pinto 2013), the Multidimensional Fatigue Inventory (MFI) (Van Vulpen 2016; Waart 2017), the Multidimensional Fatigue Symptom Inventory - Short Form (MFSI-SF) (McDermott 2017), and the Fatigue Symptom Inventory (FSI) (Brown 2017). Van Vulpen 2016 and Waart 2017 reported results...
separately for subscales of the MFI. We extracted the MFI general subscale as a comparable measure for inclusion in the meta-analysis. We chose the general subscale score as it includes general statements about fatigue and decreased functioning, designed to encompass both physical and psychological aspects of fatigue (Lin 2009). We multiplied mean scores from the MFI general subscale by minus one to ensure all scales had the same direction of effect, as discussed in the Cochrane Handbook for Systematic Reviews of Interventions section, 9.2.3.2 (Deeks 2017).

Low-quality evidence suggests an improvement in cancer-related fatigue in the physical activity group compared with the usual care group at immediate-term follow-up (MD 2.16, 95% CI 0.18 to 4.15; 6 studies, 230 participants; I² = 18%; Analysis 6.1), short-term follow-up (SMD 0.34, 95% CI 0.08 to 0.60; 7 studies, 277 participants; I² = 9%; moderate-quality evidence; Analysis 6.3), but not medium-term follow-up (SMD 0.25, 95% CI -0.16 to 0.67; 3 studies, 91 participants; I² = 0%; low-quality evidence; Analysis 6.4). Change from baseline to 12 weeks suggests no improvement in fatigue in the physical activity group compared with the usual care group (MD 0.41, 95% CI -1.33 to 2.14; 3 studies, 113 participants; I² = 70%; low-quality evidence; Analysis 6.2). There were insufficient data to conduct change from baseline analysis at all other time points. Brown 2017 reported improvements in change from baseline scores in the high dose intervention group compared with control at short-term follow-up (P trend = 0.045).

We conducted a sensitivity analysis with studies at low risk of bias and those that performed an ITT analysis at immediate- and short-term follow-up. There was no difference in fatigue between groups at immediate- or short-term follow-up (Table 1). Results from the fixed-effect sensitivity analysis were consistent with those from the random-effects model.

### Anthropometric measurements

A total of 10 studies reported anthropometric measurements assessed by: weight (Bourke 2011; Cantarero-Villanueva 2016; Courneya 2016; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016; Van Vulpen 2016), BMI (Bourke 2011; Brown 2017; Cantarero-Villanueva 2016; Courneya 2003; Lee 2017; Lewis 2016; McDermott 2017; Nuri 2016), waist measurement (Brown 2017; Cantarero-Villanueva 2016; Lee 2017; McDermott 2017), waist-to-hip ratio (Bourke 2011; Brown 2017; Lewis 2016; McDermott 2017), body fat percentage (Cantarero-Villanueva 2016; Courneya 2003; Lee 2017; Lewis 2016; Nuri 2016), and hip circumference (Brown 2017; Courneya 2016; McDermott 2017). Brown 2017 also assessed visceral fat, subcutaneous fat and fat mass.

Change from baseline to 12 weeks follow-up, but not change from baseline to 12 weeks to six months follow-up suggests a small reduction in weight (MD -1.71, 95% CI -2.90 to -0.51; 3 studies, 82 participants; I² = 1%; low-quality evidence; Analysis 7.2; Analysis 7.3) and body fat percentage (MD -1.57, 95% CI -3.11 to -0.04; 2 studies, 60 participants; I² = 0%; low-quality evidence; Analysis 10.2 and Analysis 10.4), but not BMI at either time point (Analysis 11.2; Analysis 11.4; low- and very low-quality evidence, respectively, or change from baseline up to 12 weeks for waist-to-hip-ratio (Analysis 9.2; very low-quality evidence). Low-quality evidence suggests a small reduction in waist measurement in change from baseline from 12 weeks to six months follow-up (MD -2.79, 95% CI -5.21 to -0.36; 2 studies, 70 participants; I² = 38%; Analysis 8.3). When we conducted a sensitivity analysis using a random-effects model for waist measurement, the difference between the physical activity and usual care group was no longer significant (MD -4.36 cm, -11.42 to 2.71; 2 studies, 70 participants; I² = 38%).

There was insufficient postintervention and change from baseline data at six months to 12 months to report on any anthropometric measure. Insufficient data precluded meta-analysis of change from baseline data to 12 weeks follow-up for waist measurement and more than 12 weeks to six months follow-up for waist-to-hip-ratio. We did not pool studies that measured hip circumference from 12 weeks to six months follow-up (Brown 2017; McDermott 2017), as Brown 2017 reported change from baseline scores whilst McDermott 2017 reported postintervention scores.

Courneya 2016 reported no statistically significant difference between the structured exercise programme (SEP) group and the health education materials (HEM) group for weight (SEP = 115, HEM = 112) (P = 0.38), hip circumference (SEP = 99, HEM = 99) (P = 0.09) or waist circumference (SEP = 99, HEM = 99) (P = 0.31) at one year. Between-group changes in body weight were not significantly different between intervention (n = 16) and usual care (n = 14) for both men and women in the study by Van Vulpen 2016 at 18 and 36 weeks. Changes in waist-to-hip ratio were not statistically significant in the study by Lewis 2016 (P = 0.43) or Brown 2017 (P = 0.054). Cantarero-Villanueva 2016 reported a significant change from baseline scores to eight weeks and six months between the physical activity group (n = 21) and usual care group (n = 19) for waist circumference. Changes in hip circumference up to six months were not significant in the study by Brown 2017 (P = 0.518), whilst McDermott 2017 reported an increase in hip circumference in the control group at week 12 (n = 9) and a decrease at week 24 (n = 9), but not to pre-intervention levels, whilst the intervention group decreased at week 12 (n = 11) and increased at week 24 (n = 10) but not to pre-intervention levels (P = 0.012).

We conducted a sensitivity analysis for weight, waist-to-hip-ratio, BMI and body fat percentage at immediate-term follow-up, we excluded the study by Bourke 2011 because the intervention contained a dietary advice component and the study by Nuri 2016 as an ITT analysis was not conducted. Results of the sensitivity analysis suggest no difference in effect of physical activity compared with usual care on weight, BMI, waist measurement, waist-to-hip ratio or body fat percentage. The choice of model (fixed or random) did not affect the estimates of effect at this time point. A sensitivity analysis for change from baseline to 12 weeks follow-up suggested no reduction in weight or BMI when the study by Bourke 2011 was removed. A sensitivity analysis with studies at low risk of bias was conducted for weight and BMI for change scores from 12 weeks to six months, results suggest no difference in effect of physical activity compared with usual care on weight or BMI at this time point.
Health-related quality of life (HRQoL)

A total of 10 studies reported HRQoL; seven of these studies assessed HRQoL using the Functional Assessment of Cancer Therapy-Colorectal (FACT-C; Bourke 2011; Brown 2017; Courneya 2003; Cramer 2016; Kim 2018; McDermott 2017; Pinto 2013), the Functional Assessment of Cancer Therapy-General (FACT-G; Lewis 2016), the European Organisation for Research and Treatment of Cancer Quality of life Questionnaire-Core 30 (EORTC QLQ-C30; Van Vulpen 2016; Waart 2017), the EuroQol-Visual Analogue Scales (EQ-VAS; Lewis 2016), and the Satisfaction With Life Scale (SWLS; Courneya 2003).

Moderate-quality evidence suggests a small positive effect for the physical activity group compared with the usual care group on HRQoL at immediate-term follow-up (SMD 0.36, 95% CI 0.10 to 0.62; 6 studies, 230 participants; I² = 0%; Analysis 12.1) and short-term follow-up (SMD 0.45, 95% CI 0.03 to 0.88; 7 studies, 278 participants; I² = 61%; Analysis 12.2) but no evidence of difference between groups at medium-term follow-up (SMD 0.05, 95% CI -0.37 to 0.47; 3 studies, 89 participants; I² = 0%; low-quality evidence; Analysis 12.3) or change from baseline up to 12 weeks follow-up (SMD -0.10, 95% CI -0.47 to 0.28; 3 studies, 113 participants; I² = 16%; low-quality evidence; Analysis 12.4). We observed a small positive effect on change from baseline scores at more than 12 weeks to six months follow-up (SMD 0.70, 95% CI 0.14 to 1.26; 2 studies, 58 participants; I² = 0%; low-quality evidence; Analysis 12.4). Data were insufficient to conduct a meta-analysis of change from baseline scores at more than six months to 12 months follow-up. A sensitivity analysis suggests that physical activity interventions may have a positive effect on HRQoL compared to usual care at immediate-term follow-up, (excluding the study by Bourke 2011), and including studies at low risk of bias and those that conducted an ITT analysis (SMD 0.37, 95% CI 0.07 to 0.68; 4 studies, 169 participants; I² = 0%; Table 1).

Levels of physical activity

A total of 12 studies reported on levels of physical activity, assessed objectively and subjectively. Objective physical activity was assessed by accelerometry (Brown 2017; Hubbard 2016; Lewis 2016; McDermott 2017; Van Blarigan 2019). We pooled total minutes of moderate to vigorous physical activity for the meta-analysis. Subjective physical activity was assessed by the Godin Leisure Time Exercise Questionnaire (Bourke 2011; Courneya 2003; Kim 2018; Lee 2017), the International Physical Activity Questionnaire (IPAQ; Lewis 2016), the Seven-Day Physical Activity Recall (7-day PAR) questionnaire (Courneya 2003; Pinto 2013), the Tartu Physical Activity Questionnaire (TPAQ; Courneya 2016), the Community Healthy Activities Model Programme for Seniors (CHAMPS; Courneya 2016), and the Physical Activity Scale for the Elderly (PASE; Waart 2017).

We found no evidence of difference in levels of physical activity in the physical activity group compared to usual care at immediate-term follow-up (MD -8.34, 95% CI -21.05 to 4.37; 4 studies, 94 participants; I² = 43%; very low-quality evidence; Analysis 13.1) or short-term follow-up (MD 13.50, 95% CI -56.73 to 83.74; 2 studies, 36 participants; I² = 13%; Analysis 13.4) when measured objectively using accelerometry. We found no evidence of difference in change from baseline scores up to 12 weeks between groups (SMD -0.13, 95% CI -0.77 to 0.52; 2 studies, 37 participants; I² = 0%; very low-quality evidence; Analysis 13.2).

Subjective measures of levels of physical activity suggest an increase in levels of physical activity in the physical activity group compared to the usual care group at immediate-term follow-up (SMD 0.70, 95% CI 0.38 to 1.03; 4 studies, 156 participants; I² = 0%; very low-quality evidence; Analysis 13.3), short-term follow-up (SMD 0.39, 95% CI -0.05 to 0.82; 4 studies, 176 participants; I² = 38%; low-quality evidence; Analysis 13.5) and medium-term follow-up (SMD 0.35, 95% CI 0.11 to 0.59; 3 studies, 274 participants; I² = 21%; very low-quality evidence; Analysis 13.6).

We were unable to extract data from studies by Brown 2017 and Lee 2017 because Brown 2017 reported mean change in moderate to vigorous physical activity and Lee 2017 reported moderate and vigorous physical activity separately. We emailed authors but received no response. In the study by Brown 2017, both the low dose (n = 14) and high dose (n = 12) exercise group increased their moderate to vigorous physical activity compared to the usual care group (n = 13) (P trend = < 0.001) over six months. Lee 2017 reported an increase in moderate to vigorous physical activity in the exercise group (n = 62) with no change in the usual care group at three months (group x time interaction, P < 0.01). Data were insufficient to conduct a meta-analysis for change from baseline from more than 12 weeks to six months follow-up and more than six months to 12 months follow-up for objective measures and subjective measures at all time points.

We performed a sensitivity analysis, excluding studies with dietary advice co-interventions up to 12 weeks follow-up after baseline. Objectively measured physical activity suggests no difference in levels of physical activity in the physical activity group compared to usual care in immediate-term follow-up (MD -2.84, 95% CI -12.40 to 6.73; 3 studies, 80 participants; I² = 0%; Table 1). Sensitivity analysis of subjective measures of physical activity suggest an increase in levels of physical activity in the physical activity group compared to the usual care group in immediate-term follow-up (SMD 0.68, 95% CI 0.33 to 1.02; 3 studies, 138 participants; I² = 0%; Table 1). At short-term follow-up, we included studies at low risk of bias and studies that conducted an ITT analysis; this sensitivity analysis suggests no difference between levels of physical activity in the physical activity group compared to the usual care group.

Subgroup analysis

Subgroup analyses were precluded as we were unable to extract sufficient compatible data to undertake the predefined subgroup analysis

DISCUSSION

Summary of main results

This review included 16 randomised controlled trials (RCTs) with a total of 992 participants diagnosed with non-advanced colorectal cancer. We are uncertain whether physical activity interventions improve physical function. We found no evidence of effect of physical activity interventions on disease-related mental health, anthropometric measures or levels of physical activity (measured objectively). Interestingly, when levels of physical activity were measured subjectively they were higher in the physical activity...
group compared to the usual care group at immediate-, short- and medium-term follow-up. We found no evidence of serious adverse events in the intervention or usual care groups in the eight studies that reported on adverse events. There was inconsistency in the measurement and reporting of adverse events between studies. Where reported, adverse events were generally minor. We found evidence of positive effects of physical activity interventions on physical fitness (aerobic fitness, but not other components of fitness), cancer-related fatigue and health-related quality of life (HRQoL) at immediate- and short-term follow-up but not medium-term follow-up. Only three studies reported medium-term follow-up for cancer-related fatigue and HRQoL. No studies assessed outcomes at long-term follow-up. One study that assessed fatigue and levels of physical activity at four years is currently awaiting classification (Van Vulpen 2016).

No studies reported on overall survival or recurrence-free survival. Our findings should be interpreted with caution as we rated the quality of evidence between very low to moderate overall. Further, higher quality studies are required to assess the effectiveness and safety of physical activity interventions for non-advanced colorectal cancer patients.

Overall completeness and applicability of evidence

This systematic review includes studies from nine different countries. All studies except for one were undertaken in higher-income countries (Nuri 2016). This evidence may therefore limit the applicability to low-middle income countries. All studies in this version of the review except for one, exclusively included individuals with non-advanced colorectal cancer; Courmena 2003 included four stage IV participants. The majority of studies included only participants that had finished active treatment, this was apparent across all outcomes, especially at immediate-term follow-up, limiting applicability to those undergoing active treatment. Ethnicity was only reported in three studies; these studies included mostly white people. Level of education was reported in nine studies and there was some variation in the percentage of participants educated to degree level. The physical activity interventions varied somewhat in their frequency, intensity, time, mode and duration, and because of this we are unable to ascertain optimal mode, frequency, intensity or duration of physical activity interventions for effects on the primary and secondary outcomes assessed in this review, limiting recommendations for clinical practice. We were unable to undertake subgroup analysis according to physical activity intervention or participant characteristics, cancer characteristics, treatment stages and length of time since diagnosis due to lack of comparable data, which limits applicability of findings. The objective measure of physical fitness that was used most commonly amongst included studies was the 6-minute walk test. This is not the gold standard of measuring physical fitness and has been shown to underestimate VO2 peak in cancer survivors (Schumacher 2017). This may also limit the applicability of the evidence in this population. The highest incidence of colorectal cancer occurs in people aged between 65 and 74, the mean age of participants included in this review ranged between 51 and 69, this may therefore limit the applicability of this evidence to the population with the highest incidence of colorectal cancer.

For primary outcomes, such as physical function and disease-related mental health, the greatest number of studies included in a meta-analysis at any given time point was four. These findings should be interpreted with caution due to the limited number of studies and small sample sizes, especially at longer periods of follow-up, where fewer studies were included. In addition, some of the outcome data included were not normally distributed which may have affected study results. Therefore, findings should be interpreted with caution. We were unable to undertake a meta-analysis of adverse events due to inconsistencies in measurement and reporting of this data. Less than half of the included studies reported on adverse events and four of these reported that no adverse events occurred. In future, RCTs should systematically record and report adverse events and define whether these events are 'related' or 'unrelated' to the intervention. We could not provide an analysis of effects of physical activity interventions on important outcomes, such as overall survival or recurrence-free survival because no included studies reported these outcomes. No studies assessed the long-term effects (more than 12 months follow-up) of physical activity interventions on any of the primary and secondary outcomes. One study is currently awaiting classification, which reports on four-year effects of exercise on fatigue and levels of physical activity (Van Vulpen 2016). In addition, across all outcomes, few studies conducted follow-up measurements at medium-term follow-up; these findings should be interpreted with caution.

Quality of the evidence

The quality of the findings are reported in Summary of findings 1 for the main comparison. We assessed the quality of evidence for each outcome using GRADE methodology (GRADE Working Group 2004). For the immediate-term follow-up, GRADE revealed low-quality evidence for physical function, adverse events, physical fitness (aerobic fitness) and cancer-related fatigue. Moderate-quality evidence was revealed for HRQoL (immediate-term follow-up) and disease-related mental health (anxiety and depression) at short-term follow-up. The quality of evidence for change from baseline scores and all other time points, ranged between very low to moderate quality. We downgraded the quality of evidence, namely in light of imprecision and indirectness due to the small number of studies/participants included and considering the majority of studies were conducted in participants who had finished active treatment. In addition, three studies included a health education component which may also introduce indirectness, although only one of these studies reported outcomes at immediate-term follow-up. Due to the nature of the intervention it was not possible to blind personnel or participants to the intervention, putting all studies at high risk of performance bias, which may be accentuated where participants completed subjective assessments. We found discrepancy in direction of effect of interventions when levels of physical activity were measured subjectively compared to objectively. It has been recently documented that people with cancer self-report their physical activity levels to be nearly four-fold higher when compared to objective physical activity monitoring data (Vassbakk-Brovold 2016). Most of the uncertainty in judging study bias came from a lack of clarity around allocation concealment and blinding of outcome assessors. The 'Risk of bias' table and graph are available in Figure 2 and Figure 3. In addition, some of the data included in the meta-analysis for measures of mental health, cancer-related fatigue, aerobic fitness and levels of physical activity were not normally distributed, which may have affected the quality of the evidence.
Potential biases in the review process

This systematic review included comprehensive search strategies of eight electronic databases, and four clinical trial registries. We (MMG and MAT) independently screened reference lists of all included studies and any relevant systematic reviews identified. We handsearched conference and meeting abstracts of relevant organisations and undertook data extraction and ‘Risk of bias judgement’ independently. We sent emails to seven authors of studies registered in clinical trial registries with recent completion dates and received correspondence from six of these authors. We emailed four authors of unpublished studies, two of these studies are included in this review (Lewis 2016; McDermott 2017). We sent a further 13 emails to study authors that included colorectal cancer participants alongside other cancer cohorts, to request colorectal cancer participant data separately and emailed authors to request missing data, some did not reply and exclusion of these results may also be a source of bias. We were unable to explore publication bias because there were less than 10 studies included in each comparison. The mean age of participants ranged between 51 and 69, which is markedly lower than the incidence of colorectal cancer. The review therefore does not include a cohort of the relevant population, which is a source of selection bias. Furthermore, the mean age range of participants may be indicative of participation bias, where healthier participants are more likely to agree to participate in the physical activity intervention research.

A limitation of this review is that three included studies involved additional components, e.g. healthy eating seminars and a dietary information pack (Bourke 2011), health education materials for the usual care group (Courneya 2016), and weekly education sessions on a range of topics (Hubbard 2016), which could have potential synergistic effects of exercise or physical activity on some outcomes. We investigated their effect on outcomes through exclusion in sensitivity analysis when possible.

Agreements and disagreements with other studies or reviews

To our knowledge only two other systematic reviews have investigated the effectiveness of physical activity interventions in colorectal cancer patients. One if these reviews published in 2014 included 5 RCTs and 238 patients assessing the effect of exercise on HRQoL, fatigue, physical fitness, survival and/or tumour-associated biomarkers in colorectal cancer patients (Cramer 2014b). The meta-analysis for physical fitness, fatigue and HRQoL included three studies all of which are included in our review (Bourke 2011; Courneya 2003; Pinto 2013). At short-term follow-up (corresponding to our immediate-term follow-up) authors observed improvements in physical fitness after aerobic exercise compared with controls which is in agreement with our review. Also in agreement with our review, no studies reported on survival. Conversely, authors found no evidence for short-term effects on quality of life or cancer-related fatigue, whereas we found evidence of favouring effects of physical activity interventions on these outcomes at the same time point. We also observed this effect at short-term follow-up. Cramer 2014b was unable to assess outcomes at this time point due to insufficient data. In addition, authors were unable to report on safety data, whereas we reported adverse events narratively due to the extent of variation in measurement and reporting of this outcome. The differences between these reviews are due to the time of the literature search, indeed all of our other included studies were conducted after 2014.

The second review conducted by van Rooijen 2018 highlighted the lack of evidence available on exercise training in those explicitly undergoing active treatment, which was also evident in this review. Six of the seven studies included in the van Rooijen 2018 review included mixed cancer populations, we therefore did not compare results.

AUTHORS' CONCLUSIONS

Implications for practice

We are uncertain whether physical activity interventions improve physical function compared to usual care. Physical activity interventions may have no effect on disease-related mental health. Physical activity interventions may be beneficial for aerobic fitness, cancer-related fatigue and HRQoL at immediate- and short-term follow-up. There were no serious adverse events in any of the studies that provided safety data. Where reported, adverse events were generally minor. The findings of this review should be interpreted with caution due to the low number of studies included and the quality of the evidence. Due to inconsistency in measuring and reporting of this data, more research is required to inform clinical practice. In addition, the current evidence is based on a small number of studies with few participants. The evidence is graded between low and moderate for the main outcomes, which precludes informed decision making in the clinical setting. Adequately powered RCTs of high methodological quality with longer-term follow-up are required to assess the effect of physical activity interventions on disease-related physical and mental health and on survival of people with non-advanced colorectal cancer. Adverse events should also be adequately reported. Further, it would be extremely important to understand whether certain exercise components (mode, frequency, duration and intensity) have optimal effects on physical and disease-related mental health of CRC patients both during and following active treatment.

Implications for research

This review highlights the need for further large-scale RCTs to assess the effect of physical activity interventions on the disease-related physical and mental health of people with non-advanced colorectal cancer. Future RCTs should be of high methodological quality and adequately powered, and include longer-term follow-up to investigate the sustainability of short-term benefits of physical activity. We identified only two ongoing studies that are investigating disease-free survival, recurrence-free survival and overall survival (Piringer 2017; NCT03885817) and only two studies explicitly stating "side effects of the intervention" and "safety" as outcome measures (Ho 2013; Piringer 2017). It is important for future RCTs to investigate the effects of physical activity on overall survival and recurrence-free survival and report adherence to Enhanced Recovery After Surgery (ERAS) guidelines and length of stay and systematically record and adequately report adverse events, defining whether these events are 'related' or 'unrelated' to the intervention. More research is also required exclusively in those undergoing active cancer treatment for non-advanced colorectal cancer. Indeed, RCTs undertaken with mixed cancer populations should report data separately for the specific cancers, when appropriate. More robust measures to reduce bias, especially in relation to allocation concealment and blinding of outcome assessors are required. In addition, future research should aim to recruit older participants to increase applicability of results to...
those with the highest incidence of colorectal cancer. Importantly, a better understanding of the optimal training duration, pattern, intensity, volume, setting and composition of such interventions will be needed to maximise efficacy. This requires a shift in how we record and report these components.

ACKNOWLEDGEMENTS

We would like to thank Dr Henning Keinke Andersen and Dr Kristoffer Andersen (Managing Editors), the Cochrane Colorectal Cancer Contact Editor, Dr Nicole Skoetz and Dr Daniel Steffens (peer reviewers) for their help and advice in the development of the Review protocol, Dr Aron Onerup, Dr Rasmus Dahlin Bojesen and Dr Newton Opiyo (peer reviewers) for providing feedback on the review. We would also like to thank Sys Johnsen (Information Specialist) for assisting in the development and adaptation of the search strategy and Dr Lisa A Loughney for her help and advice in the review process. We would like to thank Jill Pearson (consumer referee) and Evelyn (consumer referee) for their assistance and feedback.

MMG has been funded by the Public Health Agency, HSC R & D Division to undertake this review. **Characteristics of included studies [ordered by study ID]**

### Bourke 2011

**Methods**
- Study design: RCT
- Study location: UK

**Inclusion criteria:**
1. patients who had histologically confirmed colon cancer (Dukes stages A-C) resected 6 to 24 months previously

**Exclusion criteria:**
1. existing participation in regular physical activity (purposeful activity of at least a moderate-intensity of 30 minutes or more, 3 times a week)
2. a Karnofsky rating of less than 80
3. unstable angina
4. uncontrolled hypertension

---

**References to other published versions of this review**

**McGettigan 2017**
Bourke 2011 (Continued)

5. recent myocardial infarction, or a pacemaker

### Participants

- **Number randomised:** 18; 9 control; 9 intervention
- **Baseline imbalances:** not reported
- **Withdrawals and exclusions:** 1 dropout in intervention group (stroke)
- **Age, mean (SD) - total:** 69 years (range 52-80 years); control: 70.3 (8.7) years; intervention: 67.9 (5.7) years
- **Gender - total:** 12 male, 6 female; control: 7 male, 2 female; intervention: 5 male, 4 female
- **Ethnicity:** not reported
- **Comorbidities:** not reported
- **SES:** not reported
- **Cancer type:** colon
- **Colorectal cancer stage:** Dukes A-C
- **Type of treatment n:** surgery: 8 control, 9 intervention; chemotherapy: 2 control, 4 intervention; palliative care: 1 control, 0 intervention
- **Receiving or finished treatment:** finished
- **Time beyond treatment (months):** 16.7 control; 16.4 intervention
- **Time since diagnosis:** not reported

### Interventions

#### Physical activity description

- **Frequency:** 2 group-based supervised sessions weekly and one home-based
- **Intensity:** 55% to 85% of age predicted maximum heart rate or rate of perceived exertion between 11 and 15
- **Time:** 30 minutes of aerobic exercise per session, 2 and 4 sets of 8 to 12 repetitions of resistance exercises
- **Type:** aerobic (treadmills, rowing ergometers, and cycling ergometers) and resistance
- **Volume:** not reported
- **Progression:** during the final 6 weeks of the intervention, participants attended the university facility once a week and were asked to perform two home-based sessions a week
- **Length of intervention:** 12 weeks

#### Control group

- **Usual care**

#### Setting

- **Exercise suite in university and home-based**
- **Supervised or self-directed:** both
- **Co-interventions:** dietary advice information pack, on a fortnightly basis throughout the intervention, engaged in healthy eating seminars in a group format, lasting approximately 15 to 30 minutes

### Outcomes

1. Total exercise behaviour (Godin Leisure Score Index questionnaire)
2. Macro/micronutrient outcomes (three-day diet diaries)
3. Fatigue (FACT-F, isometric fatigue protocol was also administered at 20% of maximum voluntary torque with simultaneous assessment of motor unit recruitment using sEMG)
4. QoL (FACT-C)
5. Aerobic exercise tolerance (Bruce Protocol Treadmill Test)
6. Functional capacity (sit to stand test)
### Bourke 2011 (Continued)

- **7. Lower-limb strength (isokinetic dynamometry)**
- **Time points measured:** baseline and 12 weeks
- **Time points reported:** baseline and 12 weeks
- **Adverse events:** a stroke occurred in the intervention group

### Notes

- **Funding source:** not reported

### Brown 2017

### Study characteristics

- **Methods**
  - Study design: RCT
  - Study location: USA
  
  **Inclusion criteria:**
  1. histologically confirmed stage I-III colon cancer
  2. completed adjuvant therapy
  3. age ≥18 years
  4. written physician approval
  5. the ability to walk unaided for six minutes

  **Exclusion criteria:**
Brown 2017 (Continued)

1. history of another primary cancer (other than non-melanoma skin cancer)
2. evidence of metastatic colon cancer
3. planning to receive any additional adjuvant chemotherapy or surgery (i.e. ostomy reversal); pregnant or breast feeding
4. unable to provide baseline blood sample
5. cardiac conditions
6. any other condition which, may impede testing of the study hypothesis or make it unsafe to engage in the exercise programme

Intensity: moderate-intensity (70.7% of age predicted maximum heart rate)
Time: the initial exercise dose prescribed in week one of the study is 60 min
Type: home-based treadmill walking
Progression: low-dose and high-dose exercise groups increase their exercise to 150 min in week 1 and 300 min in week 1, respectively. Exercise increased by 30 min/week 1 as the participant successfully responds to the exercise dose prescribed in the prior week
Length of intervention: 6 months
Control group: maintained their pre-study levels of physical activity and/or followed the recommendations provided by their physician
Setting: home-based
Supervised or self-directed: self-directed
Co-interventions: none

Outcomes
1. Physical activity (accelerometry)
2. Anthropometric
3. Cardiopulmonary & Functional Status
4. Clinical outcomes
5. Quality of Life
6. Biomarkers including soluble intercellular adhesion molecule-1 (sICAM-1) and soluble vascular adhesion molecule-1 (sVCAM-1) prognostic biomarkers

Time points measured: baseline, six months
Time points reported: baseline, six months
Adverse events: graded using the Common Terminology Criteria for Adverse Events version 4.0

Notes
Funding source: National Cancer Institute and the National Center for Advancing Translational Science

Brown 2017 (Continued)

Other bias          Low risk          The study appears to be free of other problems that could put it at a high risk of bias

Cantarero-Villanueva 2016

Study characteristics

Methods
Study design: RCT
Study location: Spain

Inclusion criteria:
1. more than 18 years old
2. received curative treatment due to cancer (surgery, chemotherapy and/or radiotherapy)
3. diagnosed with grades I to III A of colorectal cancer
4. completed coadjuvant treatment

Exclusion criteria:
1. presented cancer recurrence
2. underwent previous abdominal surgeries
3. were diagnosed with concomitant conditions, such as previous lower-back pain or musculoskeletal conditions (e.g. osteoarthritis, fibromyalgia or chronic fatigue syndrome)

Participants
Number randomised: 46; 23 to the intervention group and 23 patients to the usual care group
Baseline imbalances: no significant differences at baseline
Withdrawals and exclusions: six dropouts (2 in intervention group, 4 in usual care group)
Age, mean (SD) years:
60 years (usual care: 62.3 (7.9) years, intervention: 57.5 (8.0) years)
Gender, n (%):
Total: 26 males, 14 females
usual care: male 13 (68.4%), female 8 (31.6%)
Intervention: male 13 (61.9%) female 6 (38.1%)
Ethnicity: not reported
Comorbidities: not reported
SES: University degree, n (%)
Usual care 2 (10.5%)
Intervention 6 (28.6%)
Cancer type: colon
Cancer stage n (%):
stage II 14; usual care 7 (36.8%), intervention = 7 (33.3%)
stage IIIa 26; usual care 12 (63.2%), intervention 14 (66.7%)
Type of treatment: surgery, other treatment not reported
Receiving or completed treatment: finished

Time beyond treatment, mean (SD): 13.3 months
Usual care = 14.6 (10) Months
Intervention = 12 (7.4) months

Time since diagnosis: mean (SD): 15.4 months
Usual care: 17.1 (11.3) months
Intervention: 13.8 (7.8) months

**Interventions**

**Physical activity description**
Frequency: 3 times per week
Intensity: not reported
Time: 90 minutes
Type: core stabilisation and stretching exercises
Volume, progression = 1 set of 8-10 reps to 2 sets of 10 reps
Length of intervention: 8 weeks

Control group: usual care, including written general recommendations for a healthy lifestyle
Setting: activity centre
Supervised or self-directed: supervised
Co-interventions: none

**Outcomes**

1. Physical fitness/physical function: abdominal isometric endurance (trunk-curl test), flexibility ("chair sit and reach test"), functional capacity (6-min walk test with treadmill), static balance (Flamingo Test), fitness perceived (International Fitness Scale), lower back muscle strength (dynamometry)
2. Fatigue (Piper Fatigue Scale)
3. Body composition (bioelectrical impedance analysis)
4. Pain (Brief Pain Inventory)
5. Quality of life
6. Pressure Pain Thresholds
7. Muscle structure

Time points measured: baseline, 8 weeks and 6-month follow-up
Time points reported: baseline 8 weeks and 6-month follow-up
Adverse events: reported

**Notes**
Funding source: Universidad de Granada

**Courneya 2003**

**Study characteristics**

**Methods**

- Study design: RCT
- Study location: Canada

**Inclusion criteria:**

1. surgery for colorectal cancer within the past 3 months
2. recovery from surgery as indicated by an attending physician
3. ability to understand and provide written informed consent in English
4. passed the revised Physical Activity Readiness Questionnaire (rPAR-Q; Thomas et al. 1992)
5. no contraindications to exercise as determined by a submaximal cardiorespiratory fitness test

**Exclusion criteria:** not reported

**Participants**

- Number randomised: 102; 69 to the exercise group and 33 to a waiting list control group
- Baseline imbalances: no significant differences at baseline
- Withdrawals and exclusions: 9 lost to follow-up in total (7 in intervention group 2 in control group)
- Age, mean (SD) years:
  - Total; 60.3 years
  - Control; 61.1 (9.93) years
  - Intervention; 59.92 (10.73) years
- Gender:
  - Control: 64.5% male
  - Intervention: 54.8% male
- Ethnicity: not reported
- Comorbidities: not reported
- SES:
Control group: 35% completed university; 53.6% with income > USD 40,000
Intervention group: 46.4% completed university; 65.5% with income > USD 40,000

Cancer type: colorectal cancer

Cancer stage:
Tumour stage III/IV
control; 87.1%
intervention; 77.6%

Node stage 0
control; 61.3%
intervention; 58.6%

Metastatic
control; 0
intervention; 6.9% (4 participants)

Type of treatment: 100% had surgery

Surgery alone:
control 32.3%
intervention 34.4%
surgery plus RT
control 0%
intervention 1.6%

Surgery plus CT
control 51.6%
intervention 32.6%
surgery plus RT and CT
control 16.1%
intervention 21.3%

Receiving or finished treatment: not reported (most likely a combination of both as surgery had taken place in passed 3 months)

Time beyond treatment: surgery within last 3 months

Time since diagnosis: not reported

### Interventions

#### Physical activity description

- Frequency: 3 to 5 times per week
- Intensity: 65% to 75% of heart rate maximum
- Time: 20 to 30 minutes
- Type: participants were allowed to choose the mode of exercise they preferred (e.g. swimming, cycling) but if they had no preference they were prescribed walking
- Length of intervention: 16 weeks
- Total number of exercise sessions: 48 to 80

Control group: were asked not to initiate any structured exercise over the course of the intervention (wait list)

Setting: home based

Supervised or self-directed: self-directed

Co-interventions: none

### Outcomes

1. Quality of life (FACT-C scale, FACT-G, TOI score- sum of physical and FWB subscale and colorectal subscale)
2. Satisfaction with life, measured (Satisfaction with Life scale)
3. Depression and anxiety, (CES-D scale and STAI, respectively)
Courneya 2003 (Continued)

4. Cardiovascular fitness (Modified Balke Treadmill Test)
5. Body composition (Harpenden callipers)
6. Flexibility, (sit and reach test)

Time points measured: baseline and 16 weeks

Time points reported: baseline and 16 weeks

Adverse events: not reported

Notes

Study characteristics

Methods

Study design: RCT

Study location: Canada and Australia

Inclusion criteria:

1. high risk stage II or stage III colon cancer
2. received adjuvant chemotherapy within the past 2–6 months
3. an Eastern Cooperative Oncology Group performance status of 0 or 1
4. are not currently meeting physical activity guidelines (i.e. the equivalent of 150 minutes/week of moderate-intensity exercise)
5. able to complete at least two stages of a submaximal treadmill test
Exclusion criteria: not reported

Participants
Number randomised: 273; 136 to a structured exercise programme (SEP) and 137 to health education materials (HEM)
Baseline imbalances: no significant differences at baseline
Withdrawals and exclusions: 62 excluded from primary analysis at year 1 (211 analysed; 105 in the control (HEM) group, 106 in the intervention group)
Age, n (%) analysed group:
less than 65:
Control (HEM): 71 (68%)
Intervention: 71 (67%)
Gender, n (%) analysed group:
Control (HEM) male; 46 (44%), female 59 (56%)
Intervention; male 46 (43%), female 60 (57%)
Ethnicity: not reported
Comorbidities: not reported
SES: not reported
Cancer type: colon
Cancer stage, n (%):
High risk stage II:
control (HEM): 12 (11%)
Intervention: 14 (13%)
Stage III:
control (HEM): 93 (89%)
intervention: 92 (87%)
Type of treatment: 100% received chemotherapy
Receiving or finished treatment: finished
Time beyond treatment: 2-6 months
Time since diagnosis, median (range):
Control; 12 (0-16) months
Intervention; 12 (8-17) months

Interventions
Physical activity description:
Frequency: biweekly face-to-face counselling sessions combined with supervised exercise, with the option of an additional supervised exercise session during alternate weeks
Intensity: individual choice
Time: individual choice
Type: individual choice
Volume/progression: increase recreational aerobic physical activity by at least 10 MET-hours/week from baseline in the first 6 months and sustain this change for 3 years
Length of intervention: 3 years altogether (three phases – phase 1 adoption, 2 consolidation and 3 maintenance)

Control group: health education material (HEM) intervention receive general health education materials promoting physical activity and healthy nutrition as well as standard surveillance follow-up

Setting: not reported

Supervised or self-directed: supervised or telephone support

Co-interventions: HEM

Outcomes

1. Disease-free survival
2. Overall survival
3. Patient reported outcomes (using SF-36, FACIT-F, PSQI, and HADS questionnaires)
4. Physical fitness (i.e. body mass index, hip and waist circumference, cardiovascular fitness, and physical function)
5. Physical activity levels (TPAQ)
6. Safety profile according to NCI CTCAE version 3.0
7. Correlative biological markers including biochemical and molecular markers associated with insulin-related growth factor and cytokines associated with the mechanisms of fatigue
8. Economic evaluations including cost-effective analysis and cost utility analysis
9. Predictors of physical activity adherence as assessed by Social Cognitive Determinants of Exercise questionnaire

Time points measured: baseline and 1 year

Time points reported: baseline and 1 year

Adverse events: not reported

### Cramer 2016

#### Study characteristics

| Methods | Study design: RCT  
Study location: Germany |
|----------|-------------------------------------------------|
| Inclusion criteria:  
1. Colorectal cancer  
2. UICC stage I-III  
3. Between 2-48 months postsurgery  
4. aged at least 18  
5. physical and cognitive ability to follow the yoga intervention |
| Exclusion criteria:  
1. UICC stage IV  
2. further active oncological diseases  
3. diagnosed and pharmacologically  
4. treated psychiatric disorder except for cancer-related depression or adjustment disorder pregnancy or breastfeeding |
| Participants | Number randomised: 54; 27 intervention, 27 usual care control  
Baseline imbalances: more patients in the yoga group treated with colostomy  
Withdrawals and exclusions: 6 in the intervention group and 5 from the control group dropped out  
Age (SD) (age range):  
Total 68.26 (9.69) years (40–87)  
control: 67.81 (10.37) years (40–84)  
intervention: 68.70 (9.13) years (49–87)  
Gender, n (%):  
Total; Male, 33 (61.1%) Female, 21 (38.9%)  
Control; Male, 16 (59.3%) Female, 11 (40.7%)  
Intervention; Male, 17 (63.0%) Female, 10 (37.0%)  
Ethnicity: not reported  
Comorbidities: not reported  
SES, n (%): university degree 16 (29.6%), employed full time 7 (13%), retired 35 (64.8%)  
Cancer type: colorectal; colon 24 (44.4%); rectum 29 (53.7%)  
Cancer stage:  
Stage I = 20 (37.0%)  
Stage II = 11 (20.4%)  
Stage III = 21 (38.9%)  
Type of treatment, mean (SD): |
Time since surgery 22.76 (13.09) months (range 3–46 months)

Current chemotherapy n (%)
- yes 2 (3.7%)
- No 52 (96.3%)

Receiving or finished treatment:

Prior chemotherapy n (%)
- yes 25 (46.3%)
- No 29 (53.7%)

Prior radiotherapy
- yes 12 (22.2%)
- no 42 (77.8%)

Time beyond treatment: 3-46 months postsurgery 3.7% still receiving chemotherapy

Time since diagnosis: not reported

### Interventions

**Physical activity description**

- Frequency: 1 weekly class
- Intensity: not reported
- Time: 90 minutes
- Type: Hatha yoga
- Progression: postures in each class built up on the previous ones, and difficulty and intensity levels increased during the course of the programme. Patients were encouraged to practice at home although no minimum practice time was required
- Length of intervention: 10 weeks of Hatha yoga

**Control group:** Waiting list control (usual care)

**Setting:** on-site

**Supervised or self-directed:** supervised

**Co-interventions:** none

### Outcomes

1. Health-related quality of life (FACT-C)
2. Fatigue (FACIT-F)
3. Anxiety, depression (HADS)
4. Sleep quality (PSQI)
5. Safety (number and severity of adverse events)
6. Spiritual well-being (Functional Assessment of Chronic Illness Therapy - Spirituality)
7. Body awareness/bodily dissociation (Scale of Body Connection (SBC))
8. Body efficacy expectation (Body Efficacy-Expectation Scale)
9. Qualitative Interviews

Time points measured: baseline, week 10, week 22

Time points reported: baseline week 10, week 22

Adverse events: all adverse events occurring during the study period were recorded

### Notes

Funding source: no external funding

66 (11.31) years
Control, 64.2 (11.10) years
Intervention, 67.9 (11.49) years

Gender, n (%):
Male, 27 (65.9%)
Female, 14 (34.1%)

Ethnicity: not reported
SES: not reported
Comorbidities: not reported
Cancer type: colorectal
Colorectal cancer stage: T 0-4, N 0-1, M0

Type of treatment, n, (%):
Colon surgery, yes 25 (61%), no 16 (39%)
Rectal surgery, yes 16 (39%), no 25 (61%)
Laparoscopic surgery, yes 9 (22%), no 18 (43.9%)
Chemotherapy, missing 7 (17.1%), no 27 (65.9%), yes 7 (17.1%)
Radiotherapy, missing 7 (17.1%), no 29 (70.7%), yes 5 (12.2%)
Other treatment, missing 3 (7.3%), no 35 (85.4%), yes 3 (7.3%)

Receiving or finished treatment: both
Time beyond treatment: postsurgery (in recovery period), exact time not reported
Time since diagnosis: not reported

Interventions

Physical activity description

Frequency: site 1 & 2 once weekly, site 3 twice weekly exercise
Intensity: not reported
Time: 60–90 min educational sessions
Type: cardiac rehabilitation exercise classes of aerobic and strength training
Volume: not reported
Progression: not reported
Length of programme: varied depending on site (site one: 1 hour class over 10 weeks, site two 12 weeks, site 3 twice weekly over 6 weeks)

Control group: usual care patients were given a booklet by Bowel Cancer UK (a cancer charity)—*Staying healthy after bowel cancer*

Setting: not reported
Supervised or self-directed: supervised
Co-interventions: weekly education sessions (e.g. diet, physical activity, relaxation/ stress management and cardiac-specific sessions)

Outcomes

1. Feasibility and acceptability
2. Levels of physical activity (accelerometry, Scottish Physical Activity Questionnaire)
Hubbard 2016 (Continued)

3. Quality of life (EQ5D, FACT-C)
4. Anxiety and depression (HADS)
5. Fatigue (FACIT-Fatigue)
6. Healthcare resource (seven-item self-report questionnaire developed by the research team for the purposes for the study)
7. Physical activity self-efficacy (12-item questionnaire developed by investigators of the Act Well trial
8. Risk perception (operationalisation of the concept in the context of behaviour change research)

Time points measured: baseline, weeks 6, 10, 12 (depending on site), second follow-up assessment was approximately 3 months after the participant had finished cardiac rehabilitation

Time points reported: baseline, up to 12 weeks, 3 months after completion of Cardiac rehabilitation

Adverse events: no adverse events occurred

Kim 2018

Study characteristics

Methods Study design: RCT
Study location: Korea

Inclusion criteria:
1. between 18 and 75 years of age
2. confirmed stage II to III CRC
3. completed surgery, radiotherapy, and/or chemotherapy within four weeks to two years prior to study enrolment
4. ECOG performance status of 0 or 1
5. ability to understand and provide written informed consent

**Exclusion criteria:**

1. metastatic disease
2. cardiac illness
3. any condition that would make them unsuitable for the study

---

**Participants**

- Number randomised: 71 (37 intervention, 34 usual care)
- Baseline imbalances: no significant difference at baseline
- Withdrawals and exclusions: 30 and 28 participants completed study in the intervention and control group, respectively
- Age, mean (SD):
  - control 56.8 (10.2)
  - intervention 55.7 (8.7)
- Gender n (%):
  - male control 17 (50%)
  - male intervention 18 (48.6%)
- Ethnicity: not reported
- Comorbidities: not reported
- SES (%):
  - Income > USD 3000/month control (38.2%) intervention (54.1%)
  - Married control (79.5%) intervention (75.7%)
  - Completed university control (32.4%) intervention (51.4%)
- Cancer type, n (%):
  - colon control (55.9%) intervention (73%)
  - rectal control (44.1%) intervention (27%)
- Colorectal cancer stage:
  - stage II-III;
  - stage II control (35.3%) intervention (56.8%)
  - stage III control (64.7%) intervention (43.2%)
- Type of treatment, n (%):
  - chemotherapy 98 (80.3%)
  - chemo+radiotherapy 13 (10.7%)

- Time beyond treatment, mean (SD):
  - control 10.6 months (8.4) intervention 10.8 months (5.8)
- Time since diagnosis: not reported

---

**Interventions**

**Physical activity description**

Kim 2018 (Continued)
Frequency: not reported
Intensity: moderate and vigorous intensity
Time: not reported
Type: aerobic and resistance home-based exercise e.g. brisk walking, hiking and stationary bike riding were recommended for aerobic exercise 30 min resistance exercise (12-15 reps) DVD provided
Volume: weeks 1-6 18 MET/hours per week progression: after week 6 increase to 27 MET hours per week
Length of programme: 12 weeks

Control group: usual care
Setting: home-based with four meetings with exercise trainer, telephone calls and small group sessions
Supervised or self-directed: self-directed, physical activity logs checked by exercise specialists

Outcomes
1. Quality of life
Secondary outcomes:
2. Fatigue
3. Levels of physical activity
4. Anthropometric measurements
5. Levels of physical activity

Time points measured: baseline and 12 weeks
Time points reported: baseline and 12 weeks
Adverse events: not reported

Notes
Funding source: not described

Other bias | Low risk | The study appears to be free of other problems that could put it at a high risk of bias

Lee 2017

Study characteristics

Methods
- Study design: RCT
- Study location: South Korea

Inclusion criteria:
1. resident of Seoul or Gyeonggi-do
2. between 18 and 75 years of age
3. confirmed stage II to III CRC
4. completed surgery, radiotherapy, and/or chemotherapy within four weeks to two years prior to study enrolment
5. ECOG performance status of 0 or 1
6. ability to understand and provide written informed consent
7. not planning extended absences in the three months subsequent to enrolment

Exclusion criteria:
1. evidence of recurrent or metastatic disease
2. participation in regular structured physical activity at moderate-intensity exceeding 200 min/week
3. pregnant or planning to be pregnant within six months
4. we additionally excluded ostomy patients due to lack of evidence in safety of strength training

Participants
- Number randomised: 123; (62 intervention; 61 usual care)
- Baseline imbalances: no significant difference at baseline
- Withdrawals and exclusions: 13 lost to follow-up in control group; 11 lost to follow-up in intervention group
- Age, mean (SD):
  - Total 56.3 (9.7)
  - control 56.3 (9.7)
  - intervention 56.3 (9.9)
- Gender n (%):
  - male 59 (48%)
  - male control 28 (45.9%)
  - male intervention 31 (50%)
- Ethnicity: not reported
- Comorbidities: not reported
- SES (%):
  - Income > USD 3000/month (44.7%)
  - Married (81%)
  - Completed university (48.8%)
Cancer type, n (%):
  colon 84 (68.9%)
  rectal 38 (31.1%)

Colorectal cancer stage:
  stage II-III;
  stage II (46.7%)
  stage III (53.3%)

Type of treatment, n (%):
  chemotherapy 98 (80.3%)
  chemo+radiotherapy 13 (10.7%)

Receiving or finished treatment: finished

Time beyond treatment, mean (SD):
  9.8 (6.3) months

Time since diagnosis: not reported

### Interventions

**Physical activity description:**

Frequency: encouraged to do 10,000 steps daily and daily resistance exercise programme

Intensity: of these 10,000 steps, participants were asked to complete 3000 steps as exercise that increased their heart rate up to 65% of their age-predicted maximum heart rate

Time: not reported

Type: aerobic and resistance home-based exercise e.g. brisk walking, hiking and stationary bike riding were recommended for aerobic exercise 30 min resistance exercise using their own body weight that could be performed daily at home

Volume: weeks 1-6 18 MET/hours per week

progression: after week 6 increase to 27 MET hours per week

Length of programme: 12 weeks

Control group: usual care

Setting: home based with three sessions in hospital based clinic

Supervised or self-directed: self-directed, physical activity logs checked by exercise specialists

Co-interventions: none

### Outcomes

1. Fasting insulin
2. Secondary outcomes:
3. Biomarkers
4. Physical fitness
5. Body composition
6. Levels of physical activity

Time points measured: baseline and 12 weeks

Time points reported: baseline and 12 weeks

Adverse events: not reported

#### Lewis 2016

#### Study characteristics

**Methods**
- Study design: RCT
- Study location: UK

**Inclusion criteria:**
- 1. a histologically confirmed diagnosis of colorectal cancer with Dukes stages A-C
- 2. completed cancer treatment within the last 24 months (later increased to 3 years)
- 3. be able to understand spoken and written English score of 80 or more on the Karnofsky Performance Status Scale

**Exclusion criteria:**
- 1. already meeting general physical activity guidelines of 150 min of moderate physical activity or 75 min of vigorous intensity physical activity per week
- 2. recent myocardial infarction
- 3. uncontrolled hypertension
- 4. pacemaker
- 5. unstable angina

**Participants**
- Number randomised: 28; 14 control; 14 intervention
- Baseline imbalances: no significant difference between groups at baseline

Withdrawals and exclusions:
Lewis 2016  (Continued)

Control; 3 dropouts (two at three months, one at six months)
Intervention: 5 dropouts (two at three months, three at six months)

Age, mean (SD):
Total mean age; 64.75
Control 65.5 (9.2)
Intervention 64.0 (14.8)

Gender:
Control: 7 male, 7 female
Intervention: 8 male, 6 female

Ethnicity: not reported
Comorbidities: not reported
SES: not reported
Cancer type: colorectal
Colorectal cancer stage: Dukes A-C

Type of treatment, n (%):
Surgery; 28 (100%)
Chemotherapy; 10 control (71%), 2 intervention (14%)

Receiving or finished treatment: finished treatment
Time beyond treatment: within three years of completion of treatment
Time since diagnosis, months: control 13, intervention 12 months

McDermott 2017

Study characteristics

Methods
Study design: RCT
Study location: Northern Ireland

Inclusion criteria:
1. Dukes A–C colorectal cancer patients at least 6 weeks post any type anticancer treatment, as identified by the colorectal oncologic and surgical teams.
2. males and females over 18 years of age
3. physically able to undertake the intervention
4. ambulatory and without use of a walking aid

**Exclusion criteria:**
1. still undergoing and/or scheduled for further anti-cancer treatment
2. any presence of cognitive impairment
3. pregnant or possibility of being pregnant
4. known comorbidities which would severely impact upon physical functioning or nutritional status
5. already meeting the current recommended physical activity guidelines
6. unable to understand and communicate in written and oral English

**Participants**

McDermott 2017 (Continued)

Time beyond treatment: an average of 24 months post-treatment (25 (17) months in control group; 23 (19) months in the intervention group)

Time since diagnosis: not reported

Interventions

Physical activity description:

Frequency: not reported
Intensity: moderate-intensity
Time: not reported
Type: walking and strengthening intervention
Volume: not reported
Progression: aim to reach at least 150 minutes a week of moderate-intensity aerobic activity and strengthening goal of 3 sets of 8-15 repetitions, 2-3 days a week
Length of programme: 12 weeks

Control group: usual care; participants will receive the intervention information on their last visit

Setting: home based

Supervised or self-directed: self-directed with weekly telephone calls

Co-interventions: none

Outcomes

1. Feasibility
2. Levels of physical activity (accelerometer)
3. Cardiovascular endurance (6-minute walk test)
4. Lower limb strength (timed sit to stand)
5. Quality of life (FACT-C, EQ5D-3L, PANAS)
6. Demographics
7. Anthropometric tests (BMI, height, weight, hip and waist measurements)
8. Biological markers (venous and capillary blood samples)
9. Fatigue (MFSI-SF)

Time points measured: baseline 12, 24 weeks

Time points reported: baseline 12, 24 weeks

Adverse events: not reported

Physical activity interventions for disease-related physical and mental health during and following treatment in people with non-advanced colorectal cancer (Review)

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Incomplete outcome data (attrition bias)
All outcomes
Low risk
Attrition (17%) and exclusions were reported with reasons. ITT analysis conducted.

Selective reporting (reporting bias)
Low risk
Outcomes reported are consistent with outcomes to be reported in clinical trial register.

Other bias
Low risk
Baseline imbalances present, however described appropriate allocation concealment.

Study characteristics

Methods
Study design: RCT
Study location: Iran
Inclusion criteria: not reported
Exclusion criteria: not reported

Participants
Number randomised: 30; 15 control, 15 intervention
Baseline imbalances: no significant differences at baseline
Withdrawals and exclusions: three subjects in control group who did not participate in the final examinations were excluded
Age, mean (SD): 51.56 (11.28) years
Gender: 30 (100%) males
Ethnicity: not reported
Comorbidities: not reported
SES: not reported
Cancer type: colorectal
Colorectal cancer stage: stage I-III, confirmed via email from author
Type of treatment: surgery (no other treatment reported)
Receiving or finished treatment: not reported
Time beyond treatment: between 2 and 3 months postsurgery
Time since diagnosis: not reported

Interventions
Physical activity description:
Frequency: 3 times per week
Intensity: 50% to 60% of target heart rate
Time: 45 minute (including 5 min warm up cool down and 5 minute rest)
Type: aerobic/walking
Volume: not reported
Progression:
Length of programme: 8 weeks
### Control group: usual care

- Setting: not reported
- Supervised or self-directed: not reported

### Co-interventions: participants completed the 3-day diet recall forms and were instructed to maintain normal dietary habits throughout the study

#### Outcomes

1. Leptin and ghrelin
2. Anthropometric and body composition measures (BMI, waist circumference, waist, hip ratio, fat mass, lean mass)
3. Metabolic characteristics (glucose, insulin, HOMA-IR)
4. Composition of subjects’ diets
5. Physical fitness: Rockport one mile fitness walking

- Time points measured: baseline, 8 weeks and 9 weeks (i.e. after 1 week of detraining)
- Time points reported: baseline, 8 weeks and 9 weeks (i.e. after 1 week of detraining)

#### Adverse events: not reported

### Notes

- Funding source: not reported

Van Blarigan 2019

Study characteristics

Methods

Study design: RCT
Study location: USA

Inclusion criteria:

1. stage II-III colon or rectal cancer then expanded to include stage I and stage IV
2. previous completion of cancer-directed therapy ≥ 3 months and < 2 years prior to enrolment (time after completion of treatment was dropped)
Van Blarigan 2019 (Continued)

3. disease free status at enrolment
4. ability to reliably access the Internet and a mobile phone and navigate websites
5. ability to speak and read English

**Exclusion criteria:**

1. any of 19 specific contraindications to moderate-to-vigorous physical activity
2. very active at baseline (defined as engaging in exercise for ≥ 30min for ≥ 5days a week)

**Participants**

- Number randomised: 42; 21 to intervention group, 21 to control group
- Baseline imbalances: control group more active than intervention group
- Withdrawals and exclusions: 0 lost to follow-up in intervention group, 2 in control group
- Age: 54 years (SD 11); intervention 56 (12); control 54 (11)
- Gender: male (41%) and female (59%)
- Ethnicity: white (73%), African American/black (2%), Asian (12%), other (12%)
- Comorbidities: not reported
- SES: college degree (93%), employed (63%)
- Cancer type: colon (56%), rectal (44%)
- Cancer stage: stage I (20%), II (20%), III (59%), IV (2%)
- Type of treatment: 100% surgery or surgery with adjuvant therapy 20/46 radiotherapy; 38/46 chemotherapy
- Receiving or finished treatment: finished
- Time beyond treatment: not reported
- Time since diagnosis: mean 1.5 years (SD 1.5)

**Interventions**

**Physical activity description**

- Frequency: encouraged to build up to 150 mins per week of moderate activity or 75 min per week of vigorous activity
- Intensity: moderate or vigorous
- Type: e.g. brisk walking, biking, jogging, resistance exercise
- Length of intervention: 12 weeks
- Control group: received printed educational material about exercise after cancer
- Setting: home based
- Supervised or self-directed: fit bit flex, daily text messages and counselled through print materials
- Co-interventions: none

**Outcomes**

1. Levels of physical activity (Actigraph),
2. Fitbit wear time (# days with data / # days of observation),
3. Response to text messages (# of messages responded to / # of messages that asked for a response),

**Time points measured:** baseline and 12 weeks (adverse events measured at baseline 4, 8 and 12 weeks)
**Time points reported:** baseline, 12 weeks
Adverse events: reported

Van Vulpen 2016

Study characteristics

Methods

Study design: RCT
Study location: The Netherlands

Inclusion criteria:

1. a histological diagnosis of colon cancer less than 10 wk before study recruitment
2. stage M0
3. scheduled for chemotherapy
4. age 25 to 75 yr
5. able to read and understand the Dutch language
6. Karnofsky Performance Status of 60 or higher
7. able to walk 100m or more

Exclusion criteria:

1. the presence of contraindications for physical activity (as assessed through the Revised Physical Activity Readiness Questionnaire)
2. treatment for cancer in the 5 years preceding recruitment (except for basal skin cancer)

Participants

Number randomised: 33; 17 intervention, 16 control
Baseline imbalances: participants in the intervention group were, on average, shorter and heavier

Withdrawals and exclusions: 5 lost to follow-up; 3 in control group, 2 in intervention group

Age, mean (SD):
Total mean age 58.1; intervention 58.1 (10.3); control 58.1 (9.6)

Gender, n (%):
Male; 11 (68.8%) control; 10 (58.8%) intervention
Female; 5 (31.3%) control; 7 (41.2%) intervention

Ethnicity: not reported

Comorbidities:

SES:
High-income; 9 (56.2%) control; 8 (47.1%) intervention
Married; 11 (68.8%) control; 12 (70.6%) intervention

Education; low; 3 (18.8%) control; 1 (5.9%) intervention; medium; 4 (25.0%) control; 7 (41.2%) intervention; high; 9 (56.2%) control; 8 (47.1%) intervention; unknown 1 (5.9%) intervention

Cancer type: colon
Colorectal cancer stage: stage M0

Type of treatment: 100% received surgery, 100% received chemotherapy, 18.4% received radiotherapy
Receiving or finished treatment: 81.8% undergoing chemotherapy
Time beyond treatment: majority receiving treatment
Time since diagnosis: diagnosis of colon cancer less than 10 weeks before study recruitment

**Interventions**

**Physical activity description:**

Frequency: supervised (2 times per week), unsupervised (3 times per week)
Intensity: based on heart rate at ventilatory threshold and Borg
Time: supervised (1-hour session) unsupervised (30 mins)
Type: supervised - aerobic and muscle strengthening exercise (all large muscle groups)
Volume: not reported
Progression: the muscle strengthening training started with 2 x 10 repetitions (65% 1-repetition maximum (RM) and gradually increased to reach 1 x 10 repetitions (75% 1-RM) and 1 x 20 repetitions (45% 1-RM)) by the end of the programme
Length of programme: 18 weeks

Control group: were instructed to maintain their usual physical activity pattern.

Setting: not reported

Supervised or self-directed: both

Co-interventions: none

**Outcomes**

1. Fatigue (Multidimensional Fatigue Inventory (MFI) and the Fatigue Quality List)
2. QoL, anxiety, and depression: (EORTC QLQ-C30), and a general measure of QoL, SF-36 and (HADS)
3. Physical fitness (peak oxygen uptake (VO2peak)-Cardiopulmonary exercise test, anthropometry (bodyweight and height)
4. Chemotherapy completion rate: weeks
5. Adherence (attendance percentage of the total offered class)
6. Physical activity level (short questionnaire to assess health-enhancing physical activity)

Time points measured: baseline, 18 and 36 weeks
Van Vulpen 2016 (Continued)

Time points reported: baseline, 18 and 36 weeks
Adverse events: no serious adverse events related to exercise were observed during the study period

Notes
Funding source: The Netherlands Organisation for Health Research and Development, the Dutch Cancer Society and the Dutch Pink Ribbon Foundation

Waart 2017

Study characteristics

Methods
Study design: RCT
Study location: The Netherlands

Inclusion criteria:
1. there was no upper age limit

Exclusion criteria:
1. serious orthopedic, cardiovascular, or cardiopulmonary conditions
2. were suffering from malnutrition
3. had serious psychiatric or cognitive problems
4. did not have basic fluency in Dutch

Participants
Number randomised: 23; 7 on-track, 8 onco-move, 8 usual care
Baseline imbalances: participants in onco-move were more frequently male, had lower education and more often received laparoscopic surgery while participants in on-track had less comorbidity. Participants in onco-move tended to have higher physical fitness levels than those in on-track or usual care.

Withdrawals and exclusions: on-track (n = 7) T2: 1 missing onco-move (n = 8)

T1 (1 missing for questionnaires, 2 missing physical performance tests) same at T2
UCC (n = 8) T1 (1 missing for questionnaires, 2 missing physical performance tests) T2 (none missing for questionnaires, 2 missing for physical performance tests)

Age, mean (SD):
Total 58.2 (10.1) years
On-track; 57.7 (13.2) years
Onco-move; 60.1 (7.3) years
usual care; 56.7 (10.6)

Gender, n (%):
Total 14 (61%) female
On-track; 5 (71%) female
Onco-move; 3 (38%) female
Usual care; 6 (75%) female

Ethnicity: not reported

Comorbidities, n (%): 15 (65%) of total participants

SES, n (%):
Married 16 (70%) of total
College/university education 11 (48%) of total
Full or part-time work 8 (35%) of total

Cancer type: colon

Colorectal cancer stage: stage II 3 (13%); stage III 18 (78%); stage IV 2 (9%) - author contacted correspondence received confirmed no stage IV patients were included

Type of treatment:
Larascopic surgery 12 (52%); control 2 (25%); on-track 4 (57%); onco-move 6 (75%)
Radiotherapy 1 (4%) control
Chemotherapy 23 (100%)

Receiving or finished treatment: receiving both interventions started with the first cycle of chemotherapy and continued until 3 weeks after the last cycle

Time beyond treatment: N/A

Time since diagnosis: not reported

<table>
<thead>
<tr>
<th>Interventions</th>
<th>Physical activity description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Onco-move:</td>
<td>Frequency: 5 days a week</td>
</tr>
<tr>
<td></td>
<td>Intensity: low-intensity 12–14 on the Borg Scale of Perceived Exertion participants</td>
</tr>
<tr>
<td></td>
<td>Time: at least 30 min</td>
</tr>
</tbody>
</table>
Type: not reported
On-track:
Frequency: twice weekly
Intensity: moderate- to high-intensity
Time: six large muscle groups were trained for 20 min per session in two series of eight repetitions at 80% of one-repetition maximum, 30 mins of aerobic exercises at an intensity of 50% to 80% of the predicted maximal workload of the steep ramp test. Were also encouraged to be physically active 5 days a week for 30 min and to keep an activity diary
Type: resistance and aerobic exercise
Progression: the intensity was further adjusted using the Borg
Length of programme: started with the first cycle of chemotherapy and continued until 3 weeks after the last cycle
Control group: usual care
Setting: onco-move was home based; on-track not specified
Supervised or self-directed: onco-move was unsupervised; on-track was partially supervised
Co-interventions: none

Outcomes
1. Cardiorespiratory fitness (steep ramp test)
2. Muscle strength (hand-held dynamometer for elbow flexion and knee extension and the Jamar grip strength dynamometer, and lower-limb muscle endurance with the 30-s chair stand test)
3. Fatigue (MFI)
4. HRQoL (EORTC QLQ-C30)
5. Psychological distress (HADS)
6. Self-reported physical activity (Physical Activity Scale for the Elderly (PASE))
7. Exercise behaviour and attitudes (questions about exercise stage self-efficacy, social support benefits barriers, and attitudes toward exercise during chemotherapy)

Time points measured: T0 baseline prior to chemotherapy, T1 at completion of chemotherapy, T2 6 months after completion of chemotherapy

Time points reported: as above

Adverse events: no adverse events occurred

Notes
Funding source: funding PACES was supported by the Alpe d’HuZes/KWF Fund. The research grant was provided by the Dutch Cancer Society and CZ Fund. The interventions were funded by Zilveren Kruis Achmea and The Comprehensive Cancer Centre

Waart 2017

Physical activity interventions for disease-related physical and mental health during and following treatment in people with non-advanced colorectal cancer (Review)
Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Incomplete outcome data (attrition bias)
All outcomes
Low risk
Attrition (low) reported without reasons, however it is balanced across groups

Selective reporting (reporting bias)
High risk
Study protocol included outcomes (anthropometric measurements, return to work) data that are not presented in available reports

Other bias
High risk
Due to baseline imbalances alongside unclear allocation concealment

<table>
<thead>
<tr>
<th>Study</th>
<th>Reason for exclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zopf 2018</td>
<td>Wrong study design</td>
</tr>
</tbody>
</table>

#### Methods
- RCT

#### Participants
- 57 patients (age 24 to 73 years) who had received chemotherapy for lymphomas, breast, gynaecologic, testicular, or colorectal cancer (8 CRC participants)

#### Interventions
- Intervention details: 18-week high-intensity strength training programme in cancer survivors
- Comparator details: standard care

#### Outcomes
1. Muscular strength (1-repetition maximum)
2. Cardiopulmonary function (VO₂ max)
3. Maximal short exercise capacity (MSEC)
4. Body composition
5. Health-related quality of life (HRQOL)

#### Notes
- Emailed to check whether CRC patients analysed separately

### Golsteijn 2017

<table>
<thead>
<tr>
<th>Study</th>
<th>Reason for exclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ho 2013</td>
<td></td>
</tr>
</tbody>
</table>

#### Methods
- RCT

#### Participants
- 222 colorectal cancer patients who completed curative treatment without evidence of recurrence will be recruited into the study

#### Interventions
- Intervention details: onco-active (computer-tailored physical activity intervention participants received tailored advice at 3 time points, a pedometer and access to interactive content on the website)
- Comparator: usual care waiting list control

#### Outcomes
1. Physical activity behaviour (self-report Short Questionnaire to Assess Health Enhancing Physical Activity (SQUASH) and accelerometer data) intention be physically active,
2. HRQoL (EORTC QLQ-C30)
3. Fatigue (Checklist Individual Strength)

#### Notes
- Emailed: data may be shared
### Ho 2013 (Continued)

**Interventions**

- **Arm 1:** dietary intervention (< 5 servings of red/processed meat weekly, 2 servings of refined grains daily)
- **Arm 2:** physical activity intervention (general health target - 30 minutes moderate to vigorous physical activity, 5 days per week (i.e. 10 MET-hours/week); cancer outcome target - 60 minutes of moderate to vigorous physical activity 5 days per week (i.e. 18-20 MET-hours/week))
- **Arm 3:** dietary and physical activity intervention (meeting both physical activity and dietary targets)

**Comparator:** usual care

**Outcomes**

1. Whether physical activity and dietary targets are met
2. Magnitude and mechanism of behavioural change
3. The degree and determinants of compliance
4. The additional health benefits and side effects of the intervention

**Notes**

Estimated study completion date: June 2017 emailed for information, no reply. Trial registration number: NCT01708824

### Houborg 2006

**Methods**

RCT

**Participants**

119 patients with colorectal cancer (96), diverticulitis (7) and non-malignant disease (16)

**Interventions**

- Intervention details: demanding exercises covering mobilisation, strength training of upper and lower extremities, and aerobic training
- **Comparator:** performed relaxation exercises and received hot wrappings and massage

**Outcomes**

1. Fatigue (visual analogue scale)
2. Muscular strength
3. Walking speed
4. Physical performance test
5. Physical function questions (SF-36)

**Notes**

Requested data for CRC only, received email - to respond after 1 June

### ISRCTN07465566

**Methods**

RCT

**Participants**

Adults with CRC, Duke stage A-C2, completed surgery in the past 12 months

**Interventions**

- Intervention details: physical activity consultation after baseline (lasting 1-2 hours) and one at 3 months
### Outcomes
1. Feasibility (measured by rates of recruitment, completion, adherence),
2. Change in physical activity (Actigraph)
3. Mental well-being (HADS)
4. QoL (FACT-G and FACT-C)
5. Body composition
6. Predictors of change in physical activity
7. Perceptions of cancer risk in partners
8. Fear of cancer recurrence
9. Key components of the revised theory of planner behaviour will be measured in individuals living with colorectal cancer and their partner.
10. The quality of the relationship between the individual living with cancer and their partner will be measured to test if it affects adherence to the physical activity intervention or moderates any of the intervention effects

### Notes
Emailed - no reply received

### Jacobsen 2013
#### Methods
RCT

#### Participants
460 cancer patients receiving chemotherapy representing a range of cancer diagnoses (15 colon cancer, 6 rectal/anal cancer)

#### Interventions
Intervention details:
- arm 1: stress management
- arm 2: exercise (participants were advised to participate in home-based exercise 3–5 times per week for 20 to 30 min at approximately 50% to 75% of their estimated heart rate reserve)
- arm 3: combined stress management and exercise
- comparator: usual care

#### Outcomes
1. Mental and physical well-being
2. Depression and anxiety
3. Exercise
4. Stress reduction activity

#### Notes
Unable to contact via email

### Lee 2018
#### Methods
RCT

### Moller 2015 (Continued)

**Outcomes**
- Maximal oxygen uptake ($V_{O2}$ peak)
- Psychological well-being (HADS)
- QOL (EORTC QLQ-C30)
- General well-being (SF-36)
- Perception of pain (Brief Pain Inventory)
- Leisure time physical activity level (self-reported)
- Motivational readiness and ability and barriers to engage in exercise activities 'stages of motivational readiness' 'decisional balance' and 'exercise self-efficacy' (using validated questionnaires),
- Social support and network (Multidimensional Scale of Perceived Social Support)

**Notes**
- Trial registration number: ISRCTN24901641 Emailed

---

### NCT02403024

**Methods**
- RCT

**Participants**
- 42 CRC patients who had completed surgery for local stage disease and patients who had completed surgery and any adjuvant chemotherapy for locally advanced stage disease

**Interventions**
- Intervention details: home-based walking intervention (150 minutes per week)
- comparator: usual care (waiting list control)

**Outcomes**
- Cardiopulmonary fitness ($V_{O2}$ peak during CPET test)
- Feasibility (inclusion rate, attrition rate, adherence)
- Body composition (DXA scan)
- Blood biochemistry (fasting blood samples)
- Glycaemic control (oral glucose tolerance test)
- Patient reported outcome measures (health-related quality of life by FACT-C, sleep quality by Pittsburgh Sleep Quality Index and exercise motivation by Behavioral Exercise Regulations Questionnaire)

**Notes**
- The “Interval Walking in Colorectal Cancer” (I-WALK-CRC) study: design, methods and recruitment results of a randomised controlled feasibility trial- Publication 2018

---

### NCT02564835

**Methods**
- RCT

**Participants**
- 27 CRC survivors (any stage)

**Interventions**
- Intervention details:
arm 1: yoga programme - two 90-minute classes every week for a total of 12 weeks

arm 2: physical activity - two 90-minute classes every week for a total of 12 weeks, nine resistance exercises (e.g. squats) and 8 flexibility exercises (e.g. shoulder stretch) targeted for the whole body as well as a brief warm up and cool down (walking)

comparator: usual care

Outcomes

1. Program evaluation (participant experience and satisfaction with the interventions)
2. Attention Network Test, attention and cognitive control (Digit Span, Digit Symbol Substitution Test, Trail Making Test, Attentional Function Index),
3. Functional Assessment of Cancer Therapy - Cognitive Function
4. Pro-inflammatory Markers
5. attendance, Adherence and Attrition Log
6. Safety Log
7. Demographic and Medical Information Questionnaires
8. Profile of Mood States-Brief Form
9. Mindful Attention Awareness Scale, Beliefs about Treatment

Notes

NCT02564835

Park 2015

Methods

RCT

Participants

162 early stage breast (n = 122, 75.3 %) and colorectal cancer survivors (n = 40, 24.7%) who completed primary and adjuvant treatments

Interventions

Intervention details:
arm 1: oncologists’ exercise recommendation
arm 2: oncologists’ exercise recommendation with exercise motivation package (pedometer, exercise education and exercise diary)
comparator: control

Outcomes

1. Amount of exercise participation (Godin LeisureTime Exercise Questionnaire)
2. Quality of life
3. Self-reported physical functioning (EORTC QLQ-C30)

Notes

Schulz 2002

Methods

RCT? There is a control group and exercise group, report does not specify whether participants are randomly allocated
Schulz 2002 (Continued)

Participants: 49 colon cancer patients; 24 control, 25 intervention

Interventions: Intervention details: ergometer exercise training performed once a day for approximately 40 minutes, 5 days per week for 5 weeks at a moderate training level
Comparators: control group

Outcomes: 1. Psychological parameters (EORTC QLQ-C30, FPI-R)
2. Immunological parameters

Notes: UTC via email

Schwartz 2009

Methods: RCT

Participants: 112 females with breast, lymphoma and colon cancer

Interventions: Intervention details:
- Arm 1: 12 months, aerobic exercise, moderate-intensity home-based exercise 4 days per week. The duration of each specific exercise programme ranged from 20 to 30 minutes
- Arm 2: 12 months, resistance exercise home-based exercise 4 days per week. The duration of each specific exercise programme ranged from 20 to 30 minutes
Comparators: usual care control

Outcomes: 1. Body weight
2. Aerobic capacity (12-minute walk)
3. Muscle strength (1-repetition maximum tests)
4. Body fat (dual energy x-ray absorptiometry scans)

Notes: UTC via email

Shun 2016

Methods: RCT

Participants: 128 postsurgical colorectal cancer patients; 65 control, 63 intervention

Interventions: Intervention details: 12-week home-based moderate-intensity exercise programme
Comparators: usual care, maintained their normal daily activity

Outcomes: 1. Fatigue
2. Psychological distress (depression)

Notes: Emailed, no reply received
BMI: body mass index; CRC: colorectal cancer; EORTC QLQ-C30 - European Organisation for Research and Treatment of Cancer Quality of life; FACT-C - Functional Assessment of Cancer Therapy-Colorectal; FACT-G - Functional Assessment of Cancer Therapy-General; FPI-R - Freiburg Personality Inventory; HADS - Hospital Anxiety and Depression Scale; HRQoL - health related quality of life; MET: metabolic equivalents; QoL: quality of life; RCT: randomised controlled trial; SF-36 - Medical Outcomes Study Short Form-36 General Health Survey; UTC - unable to contact

| Methods        | Study design: Randomised parallel controlled trial  
Country where study is being conducted: China |
| Participants   | **Inclusion criteria:**  
1. clinically diagnosed as colorectal cancer in stage I to III by the TNM staging system  
2. waiting for surgical treatment  
3. willing to participate in the study  

**Exclusion criteria:**  
1. secondary or recurrent cancer  
2. serious neurological or cardiovascular conditions (e.g. recent stroke)  
3. severe mental or cognitive disorders  
4. other illnesses and contraindications to exercise |
| Interventions  | Intervention details: postoperative cancer survivors in the experimental group would participate in low-intensity resistance and aerobic exercise for 7 days, supervised by an experienced physiotherapist. And then the patients would follow a 12-week moderate- to high-intensity home exercise programme  
Comparator details: will only receive conventional treatment |
| Outcomes       | 1. The FACIT (Functional Assessment of Chronic Illness Therapy) measurement system  
2. Six-minute walk test  
3. muscle strength of major muscles in upper and lower limbs  
Time points measured: day 1 preoperation, day 7 postoperation, month 3 postoperation |

Study name: Physical activity intervention for older patients during chemotherapy for colorectal cancer

**Methods**

- **Study design:** RCT
- **Country where study is being conducted:** USA

**Participants**

**Inclusion criteria:**
1. ≥ Age 60 years (no upper age limit)
2. Diagnosis of stage II-III colon or rectal cancer planned for treatment with adjuvant chemotherapy scheduled as part of standard treatment
3. Able to read English
4. Approval from their treating physician to engage in moderate-intensity physical activity
5. Patient-assessed ability to walk and engage in moderate physical activity
6. Signed, IRB-approved written informed consent

**Exclusion criteria:**
1. Other active, invasive malignancy requiring ongoing therapy or expected to require systemic therapy
2. Already walking or engaging in other physical activity > 120 minutes per week as documented via subject self-report
3. Unable to walk or engage in moderate-intensity physical activity
4. One or more significant medical conditions that in the physician's judgment preclude participation in the walking intervention

**Interventions**

- **Intervention details:** participants will take part in the Walk With Ease (WWE) programme during the course of their chemotherapy treatment. They will be requested to initiate the WWE starting on Day 1 of adjuvant chemotherapy. Participants are asked to walk at a safe and comfortable pace, increasing their minutes per day at a rate they can sustain, with the ultimate goal of 30 minutes/day for at least 5 days/week. They are asked to maintain a daily walking log that is provided to them, entering total minutes per day.

  Participants will be asked to do the walking programme independently (self-directed, not in a formal group with an instructor) throughout chemotherapy.

- **Comparator details:** standard care

**Outcomes**

**Primary outcome measures:**
1. change in fatigue (measured via PROMIS-Fatigue)
2. changes in physical function (measured via PROMIS-PF and SPPB)
3. adherence to the physical activity intervention (measured through self-reported minutes of walking per days and walking minutes per week)
4. difference in p16INK4a levels (change in p16INK4a and muscle mass measurements pre-/post-adjuvant chemotherapy)
5. change in muscle mass measurements (change in p16INK4a and muscle mass measurements)
6. association of p16INK4a and muscle mass with any differences in fatigue, physical function or QoL during chemotherapy
7. quality of life (FACT-FCSi and PROMIS-PI)
8. changes in activities of daily living
9. changes in instrumental activities of daily living
10. changes in self-efficacy (measured by PSEFSM and OEE)

**Time points measured:** baseline, 3 months, and after completion of chemotherapy (24 weeks), some outcomes measured at 1 year

NCT02538913

Study name
Exercise training for rectal cancer patients. A randomized controlled trial

Methods
Study design: RCT
Country where study is being conducted: Norway

Participants
150 people with rectal cancer

Inclusion criteria:
1. Rectal cancer
2. Planned curative LAR with preoperative radiotherapy
3. Cancer stadium I-III
4. Able to speak and understand Norwegian

Exclusion criteria:
1. Previous radiotherapy
2. Previous pelvic surgery
3. Diseases affecting the anal sphincter

Interventions
Intervention details: daily pelvic floor muscle training and individualised regular exercise training (aerobic and strength exercise) three days per week.
Comparator details: standard care

Outcomes
Primary outcome:
1. Anal incontinence (3 and 12 months postsurgery)

Secondary outcomes:
1. Urinary incontinence (3 and 12 months postsurgery)
2. Bowel and sexual dysfunction (3 and 12 months postsurgery)
3. Physiology of the anal sphincter (3 and 12 months postsurgery)
4. Quality of life (3 and 12 months postsurgery)
5. Maximal oxygen uptake (VO₂ max) (1 week pre-surgery)
6. Postoperative complications (up to 5 years postsurgery)
7. Physical activity level (1 week pre-surgery and 3 months postsurgery)
8. In-hospital time (up to 12 months postsurgery)

Time points measured: multiple time points measured see above

### NCT03064308

<table>
<thead>
<tr>
<th>Study name</th>
<th>The Assessment of the feasibility of a home based exercise programme in the older patient following major surgery (POETold)</th>
</tr>
</thead>
</table>
| Methods    | Study design: RCT  
Country where study is being conducted: UK |
| Participants | 30 participants undergoing major body surgery including those with colorectal carcinoma |

**Inclusion criteria:**

1. Male and Female patients  
2. Age greater than 70 years  
3. Patients undergoing neoadjuvant chemotherapy

**Exclusion criteria:**

1. Participation in a formal exercise regime  
2. A BMI > 35 kg/m²  
3. Active cardiovascular disease: uncontrolled hypertension (BP > 180/100), angina, heart failure (class III/IV), arrhythmia, right to left cardiac shunt, recent cardiac event  
4. Taking beta-adrenergic blocking agents  
5. Cerebrovascular disease: untreated aneurysm (large vessel or intracranial)  
6. Respiratory disease including: pulmonary hypertension  
7. Metabolic disease: hyper and hypoparathyroidism, untreated hyper and hypothyroidism, Cushing's disease  
8. Musculoskeletal or neurological disorders  
9. Family history of early (< 55 years) death from cardiovascular disease  
10. Severe rheumatoid arthritis limiting ability to perform any part of the assessment process  
11. Unable to complete the consent process

**Interventions**

- Intervention details: participants will complete a High-Intensity Functional Exercise (HIFE) programme.  
- Comparator details: standard NHS care

**Outcomes**

**Primary:**

1. Feasibility of a home-based exercise programme following surgery in the older patient

**Secondary:**

1. Maximal oxygen uptake (V\textsubscript{O2}max)  
2. Muscle architecture ultrasound
Study name: Motivational Interviewing to Increase Physical Activity behaviour in Cancer patients (MIPAClux)

Methods:
- Study design: RCT
- Country where study is being conducted: Luxembourg

Participants:
- 70 breast, endometrial or colorectal cancer participants

Inclusion:
1. cancer stage ≤ stage III
2. > 3 months after primary treatment
3. < 24 months after primary treatment
4. ECOG performance score < 2
5. signed Informed consent

Exclusion:
1. recurrent cancer
2. history of other types of cancer
3. second primary tumour
4. planned surgery within the duration of the study
5. known or obvious cognitive or psychiatric impairments
6. positive pregnancy test

Interventions:
- Intervention details: 12 motivational interviewing sessions exploring self-assessed confidence, ambivalence, and personal values concerning changes in active lifestyle
- Comparator details: standard care

Outcomes:
Primary outcome:
1. Change in physical activity behaviour
Secondary outcomes:

1. Body mass index
2. Physical fitness
3. Cost-effectiveness

Time points measured: weeks 1, 14 and 26

Starting date: 6 July 2017

Contact information:

Study name:
Novel individualized intervention for behavioral change among high-risk group cancer survivors: Physical Activities by Technology Help (PATH)

Methods:
Study design: RCT
Country where study is being conducted: USA

Participants:
42 cancer survivors of breast, prostate, lung, colorectal, cervical or oral cancer survivor

Inclusion:
1. Finished active cancer treatment at least three months ago
2. Overweight or obese and do not exercise daily
3. Do not have any physical limitation to do mild to moderate physical activities
4. Have a smart phone and actively use an email account
5. Willing to sign the consent form

Exclusion:
1. Already doing moderate to high physical activities in their daily life (rapid screener)
2. Planning to relocate within the next 4-5 weeks
3. Stage 4 cancer
4. Already using physical activity tracker or part of a physical activity programme
5. Part of another study that may interfere with our outcome of interest, unstable mental condition
6. Mental condition that prevents patient from performing the study activities and requirements
7. Pregnancy

Interventions:
Intervention details:
Arm 1: Mycoach Smart Text - personalised text messages to cell phone to help participants to increase activity
Arm 2: MyCoach via Amazon Alexa - will interact with intelligent coach to increase activity
Comparator details: control participants will self-motivate to increase physical activities
NCT03212079 (Continued)

Outcomes

Primary outcome:
1. Average number of steps

Secondary outcomes:
1. Total number and duration of activity bouts
2. Transitions between active/inactive periods
3. Daily patterns of activity

Time points measured: 5 weeks

Starting date
3 April 2017

NCT03252821

Study name
Effects of high-intensity training compared to resistance training in cancer patients undergoing radiotherapy

Methods
Study design: RCT
Country where trial is being conducted: Belgium

Participants

Inclusion criteria:
1. primary diagnosis of prostate cancer, head and neck cancer (oral cavity, pharynx, larynx, nasal cavity/sinuses, or salivary gland) or rectum cancer
2. age over 18 years
3. no distant metastases and/or disease progression
4. at least 25 scheduled radiation treatments (5 weeks)
5. ability to read, write, and speak French

Exclusion criteria:
1. uncontrolled cardiac, hypertensive or pulmonary diseases
2. uncontrolled insulin-dependent diabetes mellitus
3. neuropsychiatric disorders or orthopaedic conditions that would impair exercise participation
4. abnormal electrocardiogram

Interventions

Intervention details
Arm 1: high-intensity aerobic training group will be conducted on cycle ergometers or treadmill with heart rate measured throughout each session
Arm 2: resistance training group muscle strengthening will incorporate eight exercises targeting major muscle groups at 60% to 85% of their estimated 1-repetition maximum (1RM)

Comparator details: no intervention, usual care

Outcomes

Primary outcome measures:
### NCT03252821 (Continued)

1. Change in fatigue (FACIT-fatigue questionnaire)

**Secondary outcome measures**

1. Change in functional capacity (6-minute walk test)
2. Change in quality of life (Functional Assessment of Cancer Therapy-General)
3. Change in sleep disturbances (Pittsburgh Sleep Quality Index)
4. Change in somnolence syndrome (Epworth Sleepiness Scale)
5. Change in insomnia (Insomnia Severity Index)
6. Change in depression symptoms (Center for Epidemiologic Studies Depression Scale)
7. Change in executive functions (Trail Making Test)
8. Change in dyspnoea (Multidimensional Dyspnea Profile)
9. Adherence (Percentage of completed sessions)

Time points measured: baseline, 5 weeks for rectum cancer

### NCT03885817

**Study name** Physically active during cancer treatment (FAKT)

**Methods** Study design: RCT

Country where study is being conducted: Norway

**Participants** 64 participants with CRC radical resection within past 3 months

**Interventions** Intervention details: exercise training and nutritional guide

Comparator details: usual care

**Outcomes** Primary:

1. Patient-reported peripheral sensory neuropathy

Secondary:

1. Fatigue
2. Change in patient reported peripheral sensory, autonomic and motor neuropathy
3. Change in BMI and body composition
4. Change in blood pressure and Tx of hypertension, cholesterol, glucose
5. Change in nutritional status
6. Change in QOL
7. Physical capacity (balance, muscle strength aerobic capacity)
8. Levels of physical activity
9. Overall- and disease-free survival

### Piringer 2017

**Study name**
Phase III randomised trial of endurance exercise following adjuvant chemotherapy for colorectal cancer "aBCSG C08-II trial"

**Methods**
- Study design: RCT
- Country where study is being conducted: Austria

**Participants**
788 patients with newly diagnosed, locally advanced colorectal cancer after adjuvant chemotherapy

**Interventions**
- Intervention details: one year endurance exercise intervention
- Comparator details: usual care while maintaining habitual physical activity levels

**Outcomes**
- **Primary:**
  1. Disease-free survival
- **Secondary:**
  1. Recurrence-free survival
  2. Overall survival
  3. Physical activity end points
  4. PROMS
  5. Cost-effectiveness
  6. Utility and safety
- Time points measured: not reported

BMI: body mass index; CI: confidence interval; HRQoL: health-related quality of life; MD: mean difference; SD: standard deviation; SMD: standardised mean difference (used when studies assess the same outcome but measure it in a variety of ways).

- a Removal of studies that did not conduct an ITT analysis
- b Exclusion of studies at high risk of bias
- c Exclusion of studies with an additional intervention component
- d Results from choice of model (fixed or random) were consistent

Appendix 4. Criteria for judging risk of bias in the 'Risk of bias' assessment tool

Random sequence generation

Selection bias (biased allocation to interventions) due to inadequate generation of a randomised sequence

Criteria for a judgement of 'low risk' of bias

The investigators describe a random component in the sequence generation process such as:

1. referring to a random number table;
2. using a computer random number generator;
3. coin tossing;
4. shuffling cards or envelopes;
5. throwing dice;
6. drawing of lots;
7. minimisation*.

*Minimisation may be implemented without a random element, and this is considered to be equivalent to being random.
### Criteria for the judgement of 'high risk' of bias

The investigators describe a non-random component in the sequence generation process. Usually, the description would involve some systematic, non-random approach, for example:

1. sequence generated by odd or even date of birth;
2. sequence generated by some rule based on date (or day) of admission;
3. sequence generated by some rule based on hospital or clinic record number.

Other non-random approaches happen much less frequently than the systematic approaches mentioned above and tend to be obvious. They usually involve judgement or some method of non-random categorisation of participants, for example:

1. allocation by judgement of the clinician;
2. allocation by preference of the participant;
3. allocation based on the results of a laboratory test or a series of tests;
4. allocation by availability of the intervention.

### Criteria for the judgement of 'unclear risk' of bias

Insufficient information about the sequence generation process to permit judgement of 'low risk' or 'high risk'.

### Allocation concealment

Selection bias (biased allocation to interventions) due to inadequate concealment of allocations prior to assignment

#### Criteria for a judgement of 'low risk' of bias

Participants and investigators enrolling participants could not foresee assignment because one of the following, or an equivalent method, was used to conceal allocation:

1. central allocation (including telephone, web-based and pharmacy-controlled randomisation);
2. sequentially numbered drug containers of identical appearance;
3. sequentially numbered, opaque, sealed envelopes.

#### Criteria for a judgement of 'high risk' of bias

Participants or investigators enrolling participants could possibly foresee assignments and thus introduce selection bias, such as allocation based on:

1. using an open random allocation schedule (e.g. a list of random numbers);
2. assignment envelopes were used without appropriate safeguards (e.g. if envelopes were unsealed or nonopaque or not sequentially numbered);
3. alternation or rotation;
4. date of birth;
5. case record number;
6. any other explicitly unconcealed procedure.

#### Criteria for the judgement of 'unclear risk' of bias

Insufficient information to permit judgement of 'low risk' or 'high risk'. This is usually the case if the method of concealment is not described or not described in sufficient detail to allow a definite judgement – for example if the use of assignment envelopes is described, but it remains unclear whether envelopes were sequentially numbered, opaque and sealed.

### Blinding of participants and personnel

Performance bias due to knowledge of the allocated interventions by participants and personnel during the study

#### Criteria for a judgement of 'low risk' of bias

Any one of the following:

1. no blinding or incomplete blinding, but the review authors judge that the outcome is not likely to be influenced by lack of blinding;
2. blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken.
### Criteria for the judgement of 'high risk' of bias

- Any one of the following:
  1. no blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding;
  2. blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.

### Criteria for the judgement of 'unclear risk' of bias

- Any one of the following:
  1. insufficient information to permit judgement of 'low risk' or 'high risk';
  2. the study did not address this outcome.

#### Blinding of outcome assessment

**Detection bias due to knowledge of the allocated interventions by outcome assessors**

### Criteria for a judgement of 'low risk' of bias

- Any one of the following:
  1. no blinding of outcome assessment, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding;
  2. blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.

### Criteria for the judgement of 'high risk' of bias

- Any one of the following:
  1. no blinding of outcome assessment, and the outcome measurement is likely to be influenced by lack of blinding;
  2. blinding of outcome assessment, but likely that the blinding could have been broken, and the outcome measurement is likely to be influenced by lack of blinding.

### Criteria for the judgement of 'unclear risk' of bias

- Any one of the following:
  1. insufficient information to permit judgement of 'low risk' or 'high risk';
  2. the study did not address this outcome.

#### Incomplete outcome data

**Attrition bias due to amount, nature or handling of incomplete outcome data**

### Criteria for a judgement of 'low risk' of bias

- Any one of the following:
  1. no missing outcome data;
  2. reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias);
  3. missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups;
  4. for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk not enough to have a clinically relevant impact on the intervention effect estimate;
  5. for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes not enough to have a clinically relevant impact on observed effect size;
  6. missing data have been imputed using appropriate methods.

### Criteria for the judgement of 'high risk' of bias

- Any one of the following:
  1. reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups;
  2. for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate;
3. for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size;
4. ‘as-treated’ analysis done with substantial departure of the intervention received from that assigned at randomisation;
5. potentially inappropriate application of simple imputation.

Criteria for the judgement of ‘unclear risk’ of bias
Any one of the following:
1. insufficient reporting of attrition/exclusions to permit judgement of ‘low risk’ or ‘high risk’ (e.g. number randomised not stated, no reasons for missing data provided);
2. the study did not address this outcome.

Selective reporting
Reporting bias due to selective outcome reporting

Criteria for a judgement of ‘low risk’ of bias
Any of the following:
1. the study protocol is available and all of the study’s prespecified (primary and secondary) outcomes that are of interest in the review have been reported in the prespecified way;
2. the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were prespecified (convincing text of this nature may be uncommon).

Criteria for the judgement of ‘high risk’ of bias
Any one of the following:
1. not all of the study’s prespecified primary outcomes have been reported;
2. one or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not prespecified;
3. one or more reported primary outcomes were not prespecified (unless clear justification for their reporting is provided, such as an unexpected adverse effect);
4. one or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis;
5. the study report fails to include results for a key outcome that would be expected to have been reported for such a study.

Criteria for the judgement of ‘unclear risk’ of bias
Insufficient information to permit judgement of ‘low risk’ or ‘high risk’. It is likely that the majority of studies will fall into this category.

Other bias
Bias due to problems not covered elsewhere in the table

Criteria for a judgement of ‘low risk’ of bias
The study appears to be free of other sources of bias.

Criteria for the judgement of ‘high risk’ of bias
There is at least one important risk of bias. For example, the study:
1. had a potential source of bias related to the specific study design used; or
2. has been claimed to have been fraudulent; or
3. had some other problem.

Criteria for the judgement of ‘unclear risk’ of bias
There may be a risk of bias, but there is either:
1. insufficient information to assess whether an important risk of bias exists; or
2. insufficient rationale or evidence that an identified problem will introduce bias.
HISTORY

Protocol first published: Issue 11, 2017
Review first published: Issue 5, 2020

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We had planned to report adverse events as a dichotomous outcome. As adverse events were inconsistently measured and reported, this precluded meta-analysis. We therefore provided a narrative description of adverse events. We did not include overall survival and recurrence-free survival in our ‘Summary of findings’ table (as indicated in the protocol) because it was not reported in any of the included studies. In measures of treatment effect, we modified the description of our follow-up periods to further clarify our follow-up time points, e.g. up to 12 weeks follow-up became up to or equal to 12 weeks follow-up. We used the term ‘physical activity interventions’ throughout the review to encompass exercise interventions for readers ease. We made reference to this in the description of interventions section. We made minor changes to the data extraction form that was proposed in the protocol after testing the pre developed form on a random sample of studies. Subgroup analysis were precluded, and we therefore removed any reference to subgroup analysis from the Assessment of heterogeneity section. We made a minor amendment to the wording under the Types of participants section, as the wording inferred patients that were not treated surgically would not be included in the review; this was not the case and was an oversight by the authors during protocol development. We included three studies that had a health education component in addition to a physical activity intervention, inclusion of these studies was unforeseen and therefore not identified in the protocol. Authors met to discuss inclusion of these studies and agreed to include studies and investigate the effect of inclusion in sensitivity analysis, where appropriate. The effect of including these studies is discussed in Types of interventions, Quality of the evidence and Potential biases in the review process sections.
