7 Keywords

8 Wearable sensor. Frailty. Older adults. Physical Activity. Mobility.

9 Abstract

10 Background: Globally the population of older adults is increasing. It is estimated that by 2050 the number of  
11 adults over the age of 60 will represent over 21% of the world's population. Frailty is a clinical condition  
12 associated with ageing resulting in an increase in adverse outcomes. It is considered the greatest  
13 challenge facing an ageing population affecting an estimated 16% of community-dwelling populations  
14 worldwide.

15 Aim: The aim of this systematic review is to explore how wearable sensors have been used to assess frailty  
16 in older adults.

17 Method: Electronic databases Medline, Science Direct, Scopus, and CINAHL were systematically searched  
18 March 2020 and November 2020. A search constraint of articles published in English, between January  
19 2010 and November 2020 was applied. Papers included were primary observational studies involving; older  
20 adults aged > 60 years, used a wearable sensor to provide quantitative measurements of physical activity  
21 (PA) or mobility and a measure of frailty. Studies were excluded if they used non-wearable sensors for  
22 outcome measurement or outlined an algorithm or application development exclusively. The  
23 methodological quality of the selected studies was assessed using the Appraisal Tool for Cross-sectional  
24 Studies (AXIS).

25 Results: Twenty-nine studies examining the use of wearable sensors to assess and discriminate between  
26 stages of frailty in older adults were included. Thirteen different body-worn sensors were used in eight

27 different body-locations. Participants were community-dwelling older adults. Studies were performed in  
28 home, laboratory or hospital settings. Postural transitions, number of steps, percentage of time in PA and  
29 intensity of PA together were the most frequently measured parameters followed closely by gait speed. All  
30 but one study demonstrated an association between PA and level of frailty. All reports of gait speed  
31 indicate correlation with frailty.

32 Conclusions: Wearable sensors have been successfully used to evaluate frailty in older adults. Further  
33 research is needed to identify a feasible, user-friendly device and body-location that can be used to identify  
34 signs of pre-frailty in community-dwelling older adults. This would facilitate early identification and targeted  
35 intervention to reduce the burden of frailty in an ageing population.

46 database search strategy.

## 48 Systematic Review

### 49 1. Introduction

50 Globally the population of older adults is increasing. It is estimated that by 2050 the number of adults over  
51 the age of 60 will have almost doubled, representing over 21% of the world's population (1). This has huge  
52 implications for society not least because of the increase in physical decline and chronic illness associated  
53 with ageing.

54 Frailty is a clinical condition associated with ageing, characterised by multi-system decline resulting in an  
55 increase in adverse outcomes such as falls, hospitalisation, institutionalisation and mortality (2). It is  
56 considered the greatest challenge facing an ageing population (3,4) affecting an estimated 16% of  
57 community-dwelling populations worldwide (5) and 21.5% of over 65's in Ireland (4). Frailty is associated  
58 with, but is not an inevitable part of ageing and it is thought to be transitional. Research suggests that with  
59 intervention people can transition between stages of frailty, from pre-frail to robust and albeit to a lesser  
60 extent, from frailty to robust (6,7).

61 The association between physical inactivity and frailty is well documented (8–12). Physical activity (PA) and  
62 physical fitness are inversely related to chronic disease and all-cause mortality, including frailty (13). As a  
63 result, the World Health Organisation has developed guidelines and an action plan to promote PA, healthy  
64 ageing and reduce functional decline, with the view to reducing the burden of sequelae of inactivity on both  
65 the individual and the health system (14). More recent guidelines include advice on reducing sedentary  
66 time (15). It is thought however, that only one in four adults over the age of 18 meet guidelines for minimum  
67 activity levels (14). Results for older adults (>65 years of age) meeting the recommendations varies from  
68 zero (10) to between 15% (16) and 87% (17).

69 Traditionally, measurement of mobility and PA has relied on the use of self-reported questionnaires,  
70 surveys or diaries, or direct observation of physical performance tests, each with inherent difficulties and  
71 limitations. While these methods can be cost-effective and simple to administer they carry a risk of bias  
72 from recall, desire to perform better and participant reactivity, a well-recognised phenomenon of behaviour  
73 change due to the awareness of being observed (18).

74 Recent advances in technology provide the opportunity for objective measurement of mobility and PA  
75 through the use of wearable sensors. This allows for unbiased examination of PA patterns and behaviours  
76 which can inform guidelines and promote more widespread participation (10,19,20). Wearable sensors in  
77 the form of accelerometers, gyroscopes, pedometers or heart-rate monitors have the capacity to measure  
78 activity frequency, duration and intensity. Accelerometers measure activity counts in real time and can  
79 detect movement in up to 3 planes – vertical, antero-posterior and medio-lateral. Pedometers measure the  
80 number of steps taken and correlate well with uni-axial accelerometers (21). Gyroscopes measure changes  
81 in orientation such as rotational or angular velocity, acceleration or displacement. Heart rate monitors

82 capture indications of physical activities that do not require trunk displacement and can be used to indicate  
83 energy expenditure and PA behaviours e.g. sedentary time.

84 Considering the increasing population of older adults, ninety-five percent of who are community-dwelling  
85 (22), identifying a way for individuals to independently and objectively monitor their risk of developing frailty  
86 is vital. The aim of this systematic review is to examine the literature to explore how wearable sensors have  
87 been used to assess frailty in older adults and compare with a traditional frailty classification tool.  
88 Specifically it aims to discern which parameters of mobility and PA obtained from wearable sensors have  
89 been used to quantify frailty in older adults, the type of body-worn sensors used to provide these  
90 parameters, the sensor-placement on the body used and how the parameters of mobility and PA are  
91 associated with the discrimination of frailty stages.

## 92 2 Methods

### 93 2.1 Search Strategy

94 This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic  
95 Reviews and Meta-Analyses (PRISMA) (23) and is registered with the International prospective register of  
96 systematic reviews (PROSPERO) (registration number CRD42020163082). Using the PICO framework  
97 (Population, Intervention, Comparator and Outcome) to develop search terms, the electronic databases  
98 Medline, Science Direct, Scopus, and CINAHL were searched March 2020 by one investigator. The search  
99 was updated November 24<sup>th</sup>, 2020 to ensure all recently published articles meeting the inclusion criteria  
100 were included. The search strategy was developed in consultation with a librarian. The complete search  
101 strategy used in MEDLINE and adapted to the other electronic sources is shown in Appendix 1. Reference  
102 lists of eligible papers were manually searched for additional studies.

### 103 2.2 Study selection

104 Papers were selected if they were available in English and met the following criteria: Primary observational  
105 studies, performed in a laboratory, clinical or free-living (home/community) environment; Recruited older  
106 adults > 60 years of age; Involved the use of any consumer, research or medical-grade wearable sensor to  
107 provide quantitative measurements of mobility and/or PA, and included a standardised frailty classification  
108 tool.

109 Studies were excluded if they used non-wearable sensors (e.g. ambient sensor, smartphone application)  
110 for outcome measurement, or outlined mobility/PA algorithm or application development exclusively.  
111 Titles and abstracts were screened by one investigator. Full texts of studies identified by this review were  
112 screened for eligibility by three investigators independently. Consensus was reached through discussion.

### 113 2.3 Data Extraction

114 Data extracted from each study included first author, year of publication, number of participants and age  
115 profile, study setting, wearable sensor used; make, model and manufacturer, study objectives and  
116 methods, parameters of PA/ Mobility measured, frailty measure, reported findings and their statistical  
117 analysis. The methodological quality of the selected studies was assessed using the Appraisal Tool for  
118 Cross-sectional Studies (AXIS) (24).

### 119 2.4 Analysis

120 Due to the heterogeneity of the study methodology, methods of analysis and outcomes reported, a meta-  
121 analyses was not possible for this review.

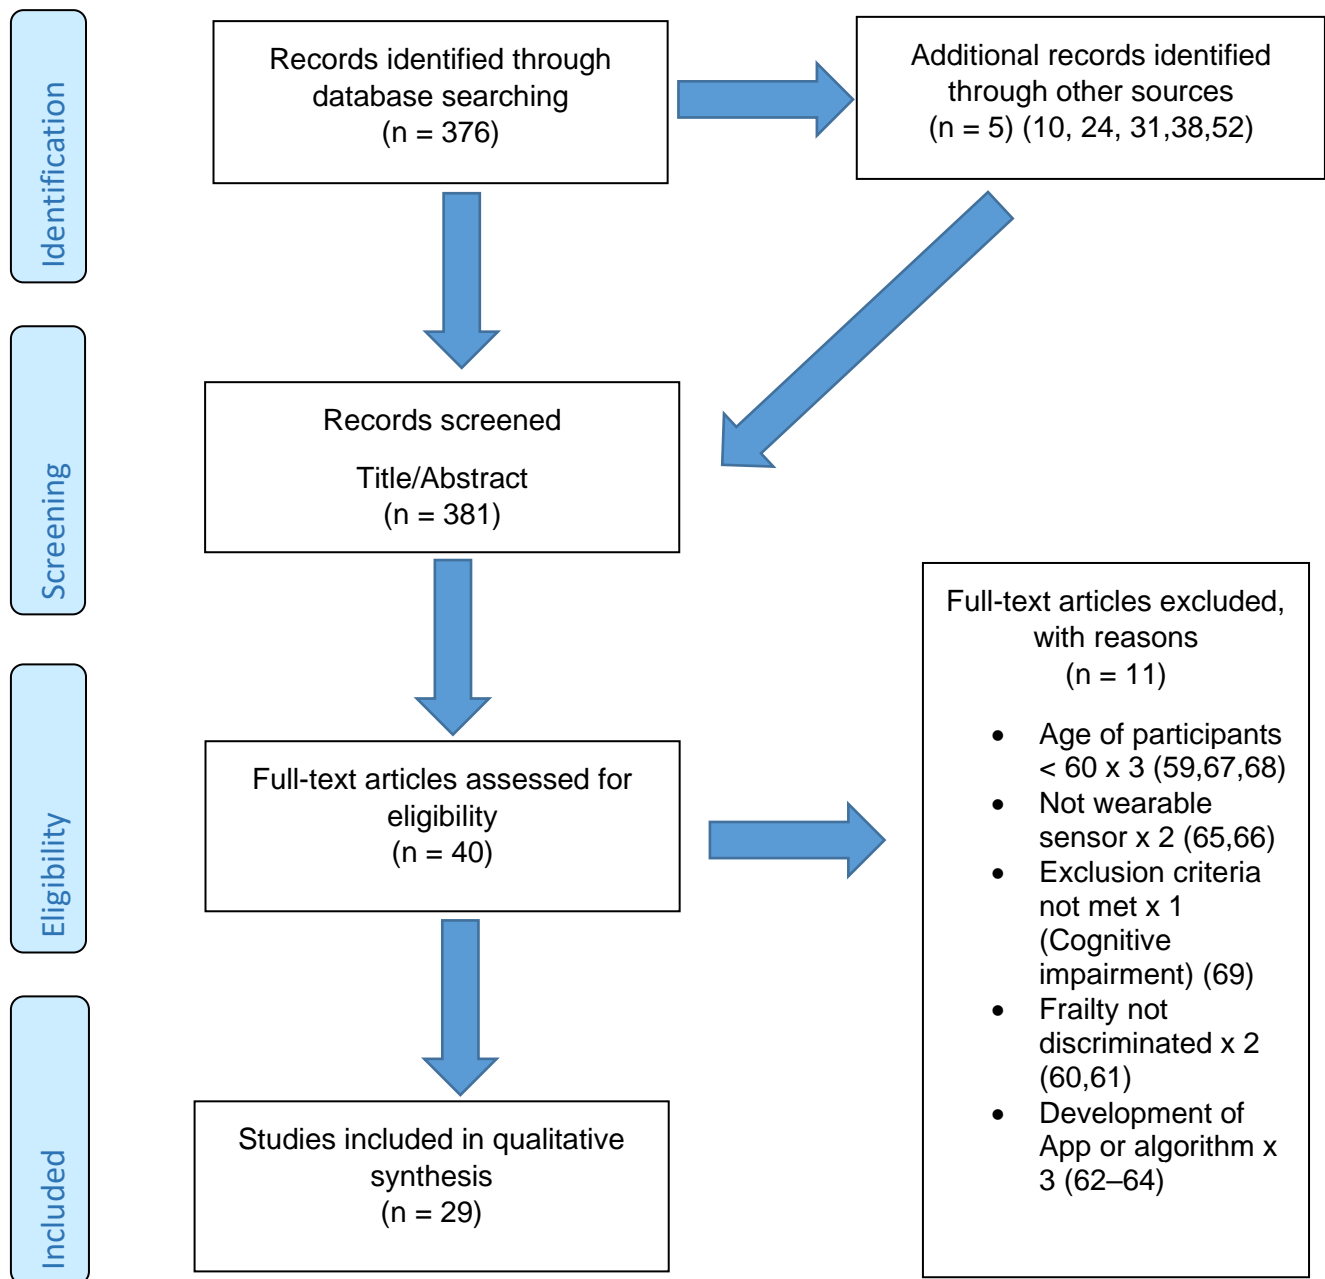

## 122 3 Results

### 123 3.1 Literature Search

124 The initial search identified 376 papers published since 2010. Following screening of titles and abstracts  
125 and removal of duplicates, 35 articles were deemed appropriate for full text screening. Five further articles  
126 were identified from manual search of references of eligible studies. One paper (25) was published after the  
127 updated search but was included when discovered incidentally. Of the 40 articles reviewed, 11 were  
128 excluded (See Appendix 2). The remaining 29 were included in the review (Table 1). Figure 1 outlines the  
129 selection process.

### 159 3.2 Study characteristics

160 All studies included in the review were either validation or observational cross-section design. One study  
161 (16) was a mixed methods design but only the objective quantitative results were included in the report.  
162 The studies were carried out in varying settings; home: n = 14 (10,16,34–37,26–33), laboratory: n = 8  
163 (31,38–44), hospital: in-patient n = 2 (45,46), out-patient n = 2 (34,47), community centre n = 1 (48) and not  
164 specified: n = 4 (25,49–51). Participant numbers ranged from n = 30 to n = 718. Criteria of frailty  
165 classification included Fried's Frailty Phenotype (n = 19) (16,25,39,40,42–44,47,49–51,27–30,32–34,38),  
166 modified Frailty Phenotype (n = 3) (35,36,48), Rockwood's Frailty Index (n = 2) (26,41) Trauma-Specific FI  
167 (n = 2) (45,46), Identification Seniors At Risk —Hospitalized Patients' questionnaire (ISAR-HP) (n = 1) (10)  
168 and Tilburg Frailty Indicator (n = 1) (31).

169 Of the studies included, 13 different body-worn sensors were used in eight different body-locations. Details  
170 of sensors are provided in Table 2. One study used an iPhone as a body-worn sensor by affixing to the  
171 chest, data from which is presented in two separate articles (40,44). Sensor placement included the lumbar  
172 spine (LSp) (n = 8), chest (n = 7), shin/ankle (n = 7), wrist and upper-limb combination (n = 3), wrist (n = 2),  
173 waist (n = 3), hip (n = 3), thigh (n = 3), foot (n = 1) and not specified (n = 3). Nineteen studies used just one  
174 body location (10,16,39–41,43,44,47–49,51,29–31,34–38), three studies, examining elbow kinetics  
175 specifically, used a combination of above elbow and wrist (28,45,46) while six others used multiple body-  
176 locations of LSp and shin (50), and chest, LSp, thigh, shin and foot (25–27,32,42).

177 [Insert Table 2 here]

178 Seven different measures of mobility and PA were reported. Mobility measures included temporal-spatial  
179 gait parameters of speed, total steps, double support, stride length, time and variability (25–  
180 27,40,42,43,47,49), postural transitions: acceleration counts of sit to stand (STS), stand to walk, stand to sit  
181 (26,29,30,39,41,42,51), trunk angular velocity (40,43), upper limb kinematics (28,45,46), intensity of PA and  
182 percentage of time in walking, standing, sitting and lying (10,16,37,48,26,27,29–32,35,36). Two studies  
183 examined PA intensity with the aim to objectively define and compare with the low PA criterion of a frailty  
184 classification tool (33,34). Balance parameters included sway of ankle, hip and centre of mass

185 (30,36,41,24) and chair-stand kinematics including number of STS cycles, acceleration and trunk  
186 displacement (39,41,42,51).

### 187 3.3 Participant characteristics

188 Participants ranging in age 63 – 90 years were recruited from community, assisted-living or hospital  
189 environments. Four studies (38,39,41,47) included a healthy young cohort (age range 18-54 years) for  
190 comparison. For those studies that reported gender there was an overall predominance of females.

### 191 3.4 Quality assessment

192 With the exception of one study that scored 12, the methodological quality of studies demonstrated a  
193 minimum result of 70% (14 out of a possible 20, range 14 - 20) using the AXIS tool (Appendix 3). Quality  
194 appraisal of all 29 studies is presented in Table 3. The tool used does not apply a numerical score or rating  
195 because of the author's assertion of the non-linear weighting of each aspect of the assessment and each  
196 section (52). No study was excluded based on methodological score.

197 [Insert Table 3 Here]

## 198 4. Discussion

199 This systematic review was undertaken to examine which parameters of mobility and PA obtained from a  
200 wearable sensor have been used to assess and quantify frailty, which type of body-worn sensors and  
201 specific body-locations have been used and how different parameters are associated with discrimination of  
202 stages of frailty. Of the 29 studies included in the review, seven different aspects of mobility and PA with a  
203 multiplicity of subdivisions were examined, using 13 different sensors on eight different body-locations.  
204 Some studies use a combination of body-locations. This heterogeneity makes comparison and analysis  
205 difficult. Studies will be discussed under headings referring to the various mobility and PA parameters,  
206 sensors used and body-location of sensors.

### 207 4.1 Parameters of Mobility and Physical Activity

#### 208 4.1.1 Physical Activity Parameters

209 Time spent in non-sedentary activity is the most commonly examined parameter of mobility and PA in the  
210 literature reviewed. Subdivisions of PA patterns and PA behaviour examined include time spent in non-

211 sedentary activity; time spent in various intensities of activity; number of postural transitions, number of  
212 bouts, length of unbroken bouts and variability in bouts of the different measurements of PA.

213 There was some commonality of metrics among the 12 studies in this group (10,16,37,48,26,27,29–  
214 32,35,36) and some consensus. Razjouyan et al., (30) agree with earlier findings of Theou et al., (26) that  
215 total time spent in non-sedentary activity correlates well with a frailty index, demonstrating significant  
216 differences between levels of frailty. This is supported by Jansen et al., (32) in a study which examines the  
217 effect of frailty levels on motor capacity and mobility performance. The authors suggest that capacity does  
218 not necessarily determine performance or function but there is a strong association between the two and  
219 frailty. These findings are contradicted by Schwenk et al., (27) who suggest that percentage of time spent  
220 walking is a poor discriminator of frailty levels. These authors (27) suggest variability in walking bouts  
221 described as more static and less complex PA combined with shorter walking bouts as a more sensitive  
222 measure of frailty. Similarly, it is suggested that sedentary time is associated with frailty (30,36) but this is  
223 refuted in another study (16).

224 Some studies measured intensity of PA, but as is common with many of the parameters in the studies  
225 included in this review, there is little consistency in how the metrics are defined or measured. Categories of  
226 PA intensity are consistent insofar as they are referred to as variations of low, medium or high  
227 (10,16,30,31,33,34,36,37,48) but how each category is defined differs, from measurement of acceleration  
228 counts per minute (10,16) to metabolic equivalents (MET) (10,30,36,37,48) and magnitude of mobility e.g.  
229 lying, sitting, walking pace (31). Counts per minute as a metric of PA intensity are not universal and there is  
230 marked disparity between the scales used (10,16,34,35).

231 There is some agreement that moderate to vigorous activity is inversely related to frailty. Those studies that  
232 differentiate between levels of frailty agree that PA intensity discriminates non-frail (NF) from pre-frail (PF)  
233 and to a lesser extent PF from frail (F) (16,30,36,37,48). This is refuted by Jansen et al (10) who found no  
234 significant between-group differences. The much lower counts per minute used in this study may account  
235 for this finding. Acceleration counts as measured in one study (26) are referred to as postural transitions or  
236 counts per minute (CPM) in others (34,35,37). One study (29) in which postural transitions are further  
237 defined as sit to stand, stand to sit, stand to walk etc. purports the ability of the number of postural

238 transitions to discriminate between levels of frailty while the others suggest discrimination between F and  
239 NF only (34,35).

240 Within the literature included in the review, the most common correlation between frailty levels and PA  
241 demonstrated are MVPA (16,30,36,37,48), bouts of PA (27,30,32,48) and total number of steps  
242 (26,30,32,37,48).

243

#### 244 4.1.2 Temporal-Spatial Parameters of Gait including Trunk kinematics

245 Seven studies (24,25,29,30,40,41,43,) examined gait speed, velocity or time to complete a walk test as part  
246 of their research. Five included gait speed with temporal-spatial parameters including step time, regularity;  
247 stride time, length regularity; percentage of time in double support and trunk kinematics of angular velocity  
248 and trunk displacement (25,27,42,43,49). One study examined trunk kinematics only, during the STS,  
249 Stand to Sit (St-Si) and turn transitions of 10-m TUG test (40,44). While there is consensus regarding the  
250 association between gait speed/velocity and the identification of frailty (25–27,40,47) there is disparity in  
251 the significance of the results. All agree on the ability of gait speed/velocity to discriminate between NF and  
252 F however the effect size varies considerably, even between studies using the same body-location (27,47).  
253 Variation in the methodology of gait speed measurement may be a contributory factor in the disparity, with  
254 distance over which speed was measured varying from 3m to 20m. One study suggests that the ability to  
255 distinguish between PF and F, arguably a more important distinction, lies within the development of models  
256 including capacity and performance (32). This study included measures of normal and fast walking speed  
257 as measures of capacity.

#### 258 4.1.3 Balance

259 Balance is measured in different ways throughout the literature varying in the nature of the assessment, the  
260 conditions under which the assessment took place and duration of each task. Those that assessed balance  
261 during a period of quiet standing did so over different time periods ranging from 10 – 40-seconds  
262 (27,38,42,50). Conditions varied between participants standing with feet together, feet semi-tandem, eyes  
263 open and/or eyes closed while another measured balance during a 30-second chair-stand exercise (39).

264 Balance was evaluated by examining displacement of trunk (27,38,39,42), hip and ankle (27,50) in  
265 anteroposterior and medial-lateral directions and during different phases of the task (39).  
266 Studies that investigated the effect of balance parameters on the identification of frailty agree on a greater  
267 anteroposterior sway in frail groups under conditions of feet together, eyes closed but no between-group  
268 significance (27,38,50). Millor et al., (39) concur to some extent in their assessment of lateral sway.  
269 However synthesis of data is difficult because of the study characteristics. These studies varied greatly in  
270 their methodology and analysis. One study (38) proposes analysis of the orientation and acceleration  
271 signal-intensity as a novel and perhaps more appropriate approach to discriminating between frailty levels  
272 than sway or power variables of balance tests. Results of this study indicate that the higher frequencies of  
273 orientation and acceleration signals in healthy populations are distinguished from the lower frequencies of a  
274 frail population.

275 One study that examined a broad range of variables suggests that the predictive validity of balance  
276 parameters is inferior to those of gait and PA parameters (27). Subsequently it has been suggested that  
277 kinematics of STS have greater sensitivity, specificity, accuracy and precision values than those of gait  
278 parameters, specifically velocity (51). This is supported by one study which, using a model combining data  
279 from balance, PA and chair kinematics, yields a higher accuracy percentage in identifying frailty than each  
280 of the individual tests (42).

#### 281 4.1.4 Upper Limb Kinematics

282 Three studies (25,37,47) examined kinematics of the upper limb, specifically the elbow, in the development  
283 of a frailty assessment tool that does not rely on gait. All agree on the ability of the variables derived from  
284 an elbow flexion/extension task to distinguish between levels of frailty.

#### 285 5. Sensors and Body- Location

286 With the exception of two studies (26,37) in which a uni-axial accelerometer was used, all studies report the  
287 use of either a tri-axial accelerometer, gyroscope or a combination of both, with the inclusion of a tri-axial  
288 magnetometer reported in eight studies (25,38–41,47,49,51). The uni-axial accelerometer was positioned  
289 at the waist and used to record steps in conjunction with acceleration counts (26) and total number of steps  
290 with PA intensity (37). The most common body-location for the tri-axial sensors was the lumbar spine

291 (27,32,38,39,42,49–51), but in other studies these sensors were positioned at the chest (26,29,30,40–  
292 42,44), shins (25,27,28,32,43,47,53), wrist (28,31,35,45,46), waist (10,48), hip (16,36) thigh (25,27) and  
293 foot (25)

294 There was some commonality with the body-locations used and metrics obtained, for example all balance  
295 parameters were obtained using a tri-axial gyroscope positioned at the LSp (27,38,39,50,53). However in  
296 some studies a sensor positioned at the LSp was used to examine temporal-spatial parameters of gait  
297 (49,51). One study used a combination of LSp and shin to measure balance parameters, presumably  
298 because the study examined open-loop and closed-loop postural control strategy (50).

299 Body-location of sensors measuring PA included wrist (31,35), hip (16,36), waist (26,48), and chest in five  
300 studies (27,29,30,32,44,53). One study in this group (27) used a combination of body-locations but reports  
301 that data for PA was retrieved from only the sensor located at the chest.

302 Correlation between accelerometer counts and step counts in one study (26) was less in the higher FI  
303 cohort, which is surprising considering both were obtained from the same device. This perhaps suggests  
304 less sensitivity in accelerometers in detecting lower intensity of movement. This supports the idea mooted  
305 that activity below a cut-off point considered in some research as non-wear time may in fact reflect low  
306 intensity activity (54). The same study (26) found that minute-by-minute accelerometer-derived step-count  
307 and acceleration-counts correlated positively with HR values. This is interesting considering as referred to  
308 previously, heart rate monitors capture indications of physical activities that do not require trunk  
309 displacement and can be used to indicate energy expenditure and physical activity behaviours e.g.  
310 sedentary time.

## 311 6. Limitations

312 While every effort has been made to ensure a thorough search of the relevant databases it is possible that  
313 some literature was missed. An updated search performed prior to journal submission reduces the risk of  
314 any over-sight. The inclusion of English-only publications may have resulted in omission of some relevant  
315 studies. Applying the age profile criteria of >60 years in the inclusion may be perceived as a limitation but  
316 this was done to optimise the literature included and is in accordance with the World Health Organization  
317 and the United Nations who have adopted >60 years in reference to older adults as opposed to the  
318 arbitrary 65 years commonly adopted (55). Due to the heterogeneity of metrics, the variation in body-

319 location of sensor placement and the difference in methods of analysis among the studies included in the  
320 review, meta-analysis was not possible. This however does not invalidate the findings. Many studies  
321 involved small numbers of participants and some combined frail and pre-frail cohorts for statistical analysis.  
322 This reduces the potential to discriminate between levels of frailty which is considered an important  
323 objective.

## 324 7. Conclusions

325 Despite its limitations, this review, the first to comprehensively synthesise data from existing research,  
326 makes a valuable contribution to identifying how wearable sensors have been utilised to assess frailty in  
327 older adults, the body-locations of sensor-placement used and the parameters of PA and mobility that best  
328 assist in the discrimination of frailty levels. The review highlights the heterogeneity of parameters examined  
329 in relation to frailty identification and the body-locations used. Measurements of PA have proved to be the  
330 most frequently used parameter when all variations of number of postural transitions, number of steps,  
331 percentage of time in PA and intensity of PA are considered. Only one study failed to demonstrate an  
332 association between PA and levels of frailty. Gait-speed was found to be the next most prevalent  
333 parameter, examined with all studies included in the review, demonstrating a correlation between walking  
334 speed and levels of frailty. A higher sensitivity compared with other mobility parameters is noted.

335 AsConsidering the facts that up to ninety-five percent of older adults are community-dwelling, not all older  
336 adults develop frailty and research suggests that older adults can transition between levels of frailty, this  
337 review highlights the need for further research to identify a feasible, user-friendly device and body-location  
338 that can be used to independently identify and objectively measure signs of pre-frailty in community-dwelling  
339 older adults. This could facilitate earlier identification and targeted intervention to reduce the burden of  
340 frailty in an ageing population.

Table 1 Data Extraction

Lead Author	Population, Frailty Classification, Setting	Objectives and Methods	Sensor and Location	Measure of Mobility / PA	Reported Findings	Quality Assessment Score																				
Martinez-Ramirez (38)	N=56 community dwelling or assisted living volunteers (28 male, 28 female).  FFP; 14 F (age: 79±4 years), 18 PF (age: 80±3 years), 24 NF (age: 40±3 years).  Laboratory	To examine signals from a tri-axial sensor during quiet standing balance tests in a frail, pre-frail and healthy population.  Participants were monitored during 10 s of quiet standing under 4 different conditions: FTO, FTC, FSO, FSC	MTx XSENS worn on lumbar spine (L3).	Postural sway (s)	Postural sway showed no significant differences among groups (NF, PF, F) under all conditions $p > 0.05$ Frail group showed greater values in FTC $p < 0.018$ compared with NF, PF.	15																				
Theou.(26)	N = 50 community dwelling female volunteers (age range: 63-90 years).  FI (Deficit model); 17 high frailty tertile, 17 moderate frailty tertile, 16 low frailty tertile.  Home	To examine the association of frailty with 5 PA assessment tools and determine if PA is different across levels of frailty.  Participants wore all sensors simultaneously during normal daily activities at home for 10 hours. Maximum voluntary exertions of Vastus Lateralis (VL) and Biceps Brachii (BB) were performed. A PA questionnaire was also administered.	ActiTrainer worn at the waist.  Polar WearLink HR monitor at the chest.  Garmin forerunner405 GPS at the wrist.  Biometrics DataLOG P3X8 EMG on VL and BB.	Acceleration counts (n) Gait speed (m/s) Total step count (n) Time in non-sedentary activity (counts/min) Bursts of VL & BB	The FI was most significantly correlated with accelerometer  <table border="1"> <thead> <tr> <th>Parameter</th> <th>r value</th> <th>p value</th> </tr> </thead> <tbody> <tr> <td>PA Minutes</td> <td>-0.617</td> <td><math>p &lt; 0.01</math></td> </tr> <tr> <td>MLTAQ</td> <td>-0.603</td> <td><math>p &lt; 0.01</math></td> </tr> </tbody> </table>	Parameter	r value	p value	PA Minutes	-0.617	$p < 0.01$	MLTAQ	-0.603	$p < 0.01$	16

**Table 2** Sensor Details

Author (Reference n.)	Sensor Type and Location
Martinez-Ramirez (38)	MTx XSENS,Xsens Technologies B.V. Enschede, Netherlands Tri-axial accelerometer, gyroscope & magnetometer worn at L3
Theou (26)	ActiTrainer Uni-axial accelerometer worn on waist Polar WearLink HR monitor worn on chest, Garmin forerunner405 GPS worn on wrist Biometrics DataLOG P3X8 EMG worn on Vastus Lateralis and Biceps Brachii
Millor (39)	MTx XSENSXsens Technologies B.V. Enschede, Netherlands Tri-axial accelerometer, gyroscope & magnetometer worn at L3
Galan-Mercant (40,44)	iPhone4 secured to chest Tri-axial accelerometer, gyroscope & magnetometer
Greene (43)	SHIMMER, Dublin, Ireland Tri-axial accelerometer & gyroscope worn on each shin
Greene (42)	SHIMMER, Dublin, Ireland Tri-axial accelerometer & gyroscope worn on each shin, lateral aspect of right thigh, Sternum above L5
Chen (33)	Active Style Pro, HJA350-IT, Omron Healthcare, Co. Ltd, Kyoto, Japan) Tri-axial accelerometer. Location not specified
Schwenk (27)	LEGSys™, BalanSens™, PAMSys™ Locomotion Evaluation and Gait System, (BioSensics, Cambridge, MA) Tri-axial accelerometer, gyroscope, magnetometer sensors worn on shanks, thighs, and L.
Martinez-Ramirez (49)	MTx XSENS,Xsens Technologies B.V. Enschede, Netherlands Tri-axial accelerometer, gyroscope & magnetometer worn at L3
Toosizadeh (50)	BioSensics LLC Tri-axial gyroscope worn on Upper Arm near Biceps muscle and wrist.
Toosizadeh (28)	BioSensics LLC Tri-axial gyroscope worn on Upper Arm near Biceps muscle and wrist.
Jansen (10)	ActiGraph GT3X+ (ActiGraph, Pensacola, Florida) and BT-Q1000XT (QStarz International Co) Tri-axial accelerometer and GPS receiver worn on waist
Toosizadeh (46)	BioSensics LLC Tri-axial gyroscope worn on Upper Arm near Biceps muscle and wrist.
Millor (51)	MTx Orientation Tracker (WSENS, Xsens Technologies B.V., Enschede, Netherlands) Tri-axial accelerometer, gyroscope & magnetometer worn at LSp3
Parvanneh (29)	PAMSys TM (BioSensics LLC, Watertown, MA, USA), Tri-axial accelerometer worn at Sternum
Huisingh-Scheetz (35)	ActiWatch Spectrum Tri-axial piezo-electric accelerometer worn on wrist
Lee (45)	LEGSys™(Biosensics LLC, Watertown, MA) Tri-axial gyroscope worn on wrist and Upper arm
Razjouyan (30)	PAMSys™ (BioSensics LLC, Watertown, MA, USA) Tri-axial accelerometer worn at sternum
Castaneda-Gameros (16)	Actigraph GT3X accelerometer (Actigraph, Pensacola, FL) worn on Hip
Jansen (32)	LEGSys™ (BioSensics, Cambridge, Mass., USA) Tri-axial accelerometer, gyroscope, magnetometer worn on shanks, thighs, and L.
Zhou (47)	LEGSys™ (BioSensics, MA, USA) Tri-axial accelerometer, gyroscope, magnetometer worn on both shins
Mulasso (31)	ADAMO System (Caretek S.r.l., Turin, Italy) Tri-axial accelerometer worn on wrist
Lepetit (41)	APDM (Opal, Portland, USA) Tri-axial accelerometer, gyroscope, magnetometer worn on chest
Yuki (37)	Lifecorder (Suzuken, Aichi, Japan)

	Uniaxial accelerometer. Body-location not specified
Ziller (34)	ActiGraph wGT3x-BT Tri-axial accelerometer worn at hip
Chen (48)	Active style Pro HJA- 350IT, Omron Healthcare, Kyoto, Japan. Triaxial accelerometer worn at the waist
Kikuchi (36)	Active style Pro HJA-750C; Omron Healthcare, Kyoto, Japan. Triaxial accelerometer worn at the hip
Apsega (25)	SHIMMER, Dublin, Ireland Tri-axial accelerometer & gyroscope worn on each thigh, shin and dorsum of foot

382 **Appendix 2 Excluded studies**

Author and year	Reason for exclusion
Mueller (60)	Proof of concept study. Doesn't use parameters to identify frailty
Keppler (61)	Not frailty
Chigateri (62)	Comparing algorithm with video
Soaz (63)	Validation of step-detection algorithm
Fontecha (64)	Development of app
Da Silva (65)	Used non-wearable sensors
Chkeir (66)	Used non-wearable sensors
Thiede (59)	Population studied aged < 60 year
Zhong (67)	Population studied aged < 60 year
Rahemi (68)	Population studied aged < 60 year
Martinez-Ramirez (69)	Population studied included people with cognitive impairment

383

384 **Appendix 3. AXIS TOOL**

385 **AXIS Critical Appraisal Tool** Yes [1] / No [0] / Don't Know [0]

386 **Introduction**

387 1 Were the aims/objectives of the study clear?

388 **Methods**

389 2 Was the study design appropriate for the stated aim(s)?

390 3 Was the sample size justified?

391 4 Was the target/reference population clearly defined? (Is it clear who the research was about?)

392 5 Was the sample frame taken from an appropriate population base so that it closely represented the  
 393 target/reference population under investigation?

394 6 Was the selection process likely to select subjects/participants that were representative of the  
 395 target/reference population under investigation?

396 7 Were measures undertaken to address and categorise non-responders?

397 8 Were the frailty assessment tool and outcome variables measured appropriate to the aims of the study?

398 9 Were the frailty assessment tool and outcome variables measured correctly using instruments/  
 399 measurements that had been trialled, piloted or published previously?

400 10 Is it clear what was used to determined statistical significance and/or precision estimates? (e.g., p  
 401 values, CIs)

402 11 Were the methods (including statistical methods) sufficiently described to enable them to be repeated?

## 403 **Results**

404 12 Were the basic data adequately described?

405 13 \*Does the response rate raise concerns about non-response bias?

406 14 If appropriate, was information about non-responders described?

407 15 Were the results internally consistent?

408 16 Were the results for the analyses described in the methods, presented?

## 409 **Discussion**

410 17 Were the authors' discussions and conclusions justified by the results?

411 18 Were the limitations of the study discussed? Other

412 19 \*Were there any funding sources or conflicts of interest that may affect the authors' interpretation of the  
413 results?

414 20 Was ethical approval or consent of participants attained?

415 \*Negative answer results in 'Y' Yes = 0; No = 1
